it is evident that if we put x for (b^3) and W for a and l^3 for z and c for w , then if W increases or diminishes so will x increase or diminish as soon as we operate on l^3 , in order to reduce W to one, but of course not before. If any one wishing to adopt the foregoing formula for practice should think the sectional obtained thereby to be larger or smaller than they would like to adopt, they could, by varying the constant, increase or diminish them as they might choose, or as the kind of timber they might use might require; because the constant 20 were made, say, 15, it would give $\frac{1}{3}$ increase to the sectional area, and the same would follow with any proportion as, say, put 25 or 20, then $\frac{1}{5}$ of the sectional area would do, $\frac{1}{5}$ being deducted as unnecessary in consequence of the increased power of c , now = 20, but then some other number. With respect to making an allowance for notching the back of the principal rafter, the diminution in strength in large scantlings is small, but not necessarily so large in larger ones, and may be made much, little, or nothing, according to the views of the designer. With respect to considering the extra strength derived by the coaking down of the purlins, it will be well to remember that we must not trust too much to that, because we should not dare to cut the principals across where the purlins came, and trust to the latter to keep the former to their work, and especially when we recollect the butts of the purlins will be cut over the backs of the principal rafters which will materially weaken their tying power, and more especially as the two or three nails on the top may not permanently hold very much, and if the principal is not originally straight it has always a tendency to bend on one side, and might overcome the slight resistance of perhaps a hip at the other end of the purlin, perhaps none too well nailed. If the foregoing fails to make the formula plain to "Nil Desperandum," I do not think I can add more; but if he thinks he can see any fallacy in it and will be kind enough to prove same in figures I shall be glad to reply if necessary.—HENRY AMBROSE.

[5745].—**Wood Roofs.**—I do not quite see what difference between the sectional areas is meant by "Nil Desperandum," as being so great; perhaps he will explain.—G. H. G.

[5753].—**Abutments.**—Henry Ambrose will find, if he will examine his paper, in last week's *Building News*, carefully, that he has made a mistake in his reply to the above question. Spence's "Pocket Book" gives the formula for thickness of abutment

$$T = \sqrt{\frac{1}{3} R^2 + \frac{3}{5} R^{\frac{3}{2}} + \left(\frac{W}{H}\right)^2 - \frac{W}{H}}$$

Taking Henry Ambrose's figures, viz.,
16ft. for Radius ... R in Formula
10ft. Height to Springing of Arch H , do.
40cwt. Weight of 1ft. Length of } W , do.
Half Arch

and substituting them for the letters, then the equation will read—

$$T = \sqrt{\frac{1}{3} 16^2 + \frac{3}{5} 16^{\frac{3}{2}} + \left(\frac{40}{10}\right)^2 - \frac{40}{10}}$$

$$= T = \sqrt{51 \cdot 2 + 38 \cdot 4 + 16 - 4}$$

$$= T = 10 \cdot 27 - 4$$

$$\therefore T = 6 \cdot 27 \text{ ft.}$$

or 6ft. 3in. nearly = thickness of abutment. He will find that the one decimal fifth power of 16 or $16^{\frac{1}{5}}$ is 64, and not 202, as he has it. The following is, I think, a simpler way of finding it than the method he shows:—

$$\text{Log. of } 16 = 1 \cdot 204120$$

$$\frac{1}{5} \text{ Multiply by power}$$

$$1 \cdot 806180 = \text{Log. } 64$$

Again, he has taken the $\frac{2}{3} R^3$ instead of the $\frac{3}{5}$ of it.—W. J. P.

[5757].—**Lime and Portland Cement.**—I should say the mixture of lime-mortar with Portland cement made a good pointing.—G.

[5759].—**Timber Verandah.**—Red or yellow pine or pitch-pine is preferable to oak for outside woodwork. The wood may be simply varnished, or painted with the Silicate Company's paint. I should prefer the latter, as the most durable protective.—G. H. G.

[5760].—**Carrying Weight of Floor.**—If the beams have been cut and reversed so as to insure their roundness, I would trust such a floor with from 2 to 2½cwt. per foot superficial; it will bear, say, 1½cwt. per foot with safety without much deflection.—G. H. G.

[5760].—**Carrying Weight of Floor.**—A pitch-pine beam, 16in. \times 9in., and bearing = 18ft., will carry, including its own weight, as discovered by the following working:—A piece of pitch-pine 1in. square will carry a safe load of 1½cwt. on its centre between supports 12in. apart, and provided the ends are near the supports. We will, for simplification, suppose 1cwt. instead of 1½cwt., and add $\frac{1}{2}$ of our result when obtained to compensate for same. Then 9in. wide and 1in. thick will support under similar conditions 9cwt., and 9in. wide and 16in. deep will carry $9 \times 16 \times 16 = 2304$ cwt., = $\frac{1}{2}$ safe load on centre between supports 12in. apart, and $2304 \div 18 = 128$ cwt. = $\frac{1}{2}$ of the safe load on centre between supports

18ft. apart, therefore the safe load on the centre will be 100cwt., or equal to 8 tons, or 16 tons will be the safe equally distributed load, but care must be taken that an equally distributed load so called does not place more than its proper proportion on or near the centre because otherwise 16 tons would no longer be safe. Now to find the carrying power per foot superficial I shall take as being near enough the girders as 10ft. from centre to centre, and first deduct the weight of the floor itself from our equally distributed load, the floor itself being an equally distributed load. If I were deducting the weight of the floor from a load on the centre, then I should take only half its weight, because the other half would be carried by the walls or supports, but our assumed equally distributed load is assumed already to be half carried by the walls. We shall have girder 18ft. \times 16in. \times 9in., and = 18ft. cube and 15 joists 10ft. \times 9in. \times 3in. = 43ft. cube, and 180ft. of 1in. flooring reduced to cubic feet = 15ft. cube = 61ft. together. A foot may weigh 42lb. = 2,562lb. = say, 23cwt., therefore deduct, say, a ton from the 16 tons equally distributed safe load, which leaves same 15 tons or 30cwt., and our floor space is equally to 180ft. superficial, therefore $300 \div 180$ will give 1cwt. 7½lb. as the weight per foot superficial, which will be a safe load or 1cwt. 2½lb.—HENRY AMBROSE.

[5761].—**Built Girder.**—The thicker plate should be placed on the top, and the working sectional area of the top flange should be to the working sectional area of the bottom flange, as, say, 7 to 4. Then for a 31ft. bearing we have two rolled joists, 16in. \times 6in. \times ½in. web, with a top plate 14in. \times ½in., and a bottom plate 14in. \times ½in., and the whole riveted together. Let us suppose the area of the flanges of rolled joists to be each 5in. Then the top flange will be 14in. \times ½in. \times 5in. \times 2in. = 104 + 10 = 203in. The area of the bottom flange of girder will be = $(14 \times \frac{1}{2} + 5 \times 2) = 17$ in. minus the rivet holes. Let these be four each, $\frac{1}{4} \times 13$ in. = say, 5in. Then 17 - 5 = 12in. = area of bottom flange. Then $\frac{1}{2}$ of 203in. as the working area of bottom flange, or to simplify, call 20½, say, 21, then $\frac{1}{2}$ of 21 = 12, and 12 is the most we can consider as the working bottom flange. If we have less then we consider what we have, while if we have more we do not consider the excess. Thus we have a girder 16in. deep, with a 12in. area bottom flange, and by applying Fairbairn's formula where W = breaking weight in tons on the centre, and c is a constant 80 for a box girder, and a = area of bottom flange in inches, and d = depth in inches, and l = length in inches, we have $c \frac{a \cdot d}{l} = W = 80 \times 12 \times 16 = W \therefore \frac{15360}{372} = W = 41 \therefore 41$ tons is the assumed breaking weight on the centre, and 10 tons may be assumed as the safe load on the centre, and 20 tons may with safety be equally distributed; but care must be taken to render it certain that not more than a fair proportion of the so-called equally distributed weight shall bear on or near the centre, otherwise the 20 tons may no longer be considered safe.—HENRY AMBROSE.

STAINED GLASS.

CIRENCESTER.—A stained glass window has been placed in the Trinity Chapel, of the parish church, in memory of the late Mrs. Cripps. It consists of four lights occupied respectively by full length figures of St. Joseph, the Virgin Mary, Simeon, and Anna. Beneath the window is a memorial engraved brass plate. Some ancient glass has been displaced to make way for the new window, and this has been temporarily placed in one of the windows of the Lady Chapel. The work has been carried out by Messrs. Hardman and Co., of Birmingham. A local journal states that there is a considerable quantity of stained glass taken from different parts of Cirencester Church stored in one of the rooms over the Town Hall, and the suggestion is made that this should be arranged and replaced in the Lady Chapel.

STATUES, MEMORIALS, &c.

BARNSTABLE.—On Thursday last, shortly after seven o'clock, the fountain in the Square was set playing. The structure commences with an octagonal base of granite, the top of which is about 3ft. from the ground. Surmounting this is a plinth and shaft, with carved base and capital, supporting a large basin, which is 5ft. 9in. in diameter, and the lower part of which is moulded from the edge of the basin, diminishing to the centre. The upper part of the basin is moulded, and divided into four parts, a lion's head marking each division. Above this there is a small basin, 2ft. 4in. in diameter, supported by a twisted shaft and a carved octagonal base, and surmounted by a carved capital. At the base of the fountain there is a rockery, in the pond, which is enclosed by a low circular parapet. The best Portland stone has been used for the work, the carving has been done by Messrs. Algar and Pickard, sculptors, of Exeter, and the work has been carried out by Mr. J. Pulsford, of Barnstable. The fountain was designed by Mr. R. D. Gould, the borough surveyor.

EXETER.—A tablet was on Wednesday week erected against the north wall of the nave aisle of Exeter Cathedral to the memory of the late Dr. Wesley, who was for seven years the organist of the Cathedral. The memorial is of white statuary marble, and is Early English in design. It is the work of Mr. Burke, of 17, Newman-street, London.

The Wandsworth District Board of Works have raised the salary of Mr. Barber, surveyor for the parishes of Tooting and Streatham, by £60 per annum.

WATER SUPPLY AND SANITARY MATTERS.

THE WATER SUPPLY OF LONDON.—A deputation of metropolitan ratepayers waited upon Mr. Cross last week, to ask that the Government should take up the question of the water supply of the metropolis. The Home Secretary remarked that the deputation supplied him with no figures showing how the purchase of the present companies could be accomplished. Mr. Watherston said a scheme had been prepared, and would be produced at the proper time. Mr. Cross said they must first consider the terms which the companies would be inclined to accept, and that was all he should say at present.

Our Office Table.

ON Monday last the auction bills which have recently decorated "The White House" in Tite-street, Chelsea, were hastily removed. They had announced the public sale of Mr. James A. M. Whistler's effects and residence on Tuesday morning. The painter effected an "arrangement" with his creditors, it is supposed, or, at any rate, managed, at the last moment, to postpone the sale. Mr. George Lewis, the solicitor, has presented a petition for liquidation on behalf of Mr. Whistler, whose debts amount to about £4,500. The assets are not stated, but the figures on both sides will probably hardly result in a "harmony in black and white," or even in gold and silver.

No less than five large mansions are now in course of erection on the Embankment at Chelsea from the designs of Mr. R. Norman Shaw, whose works stand out from the similar buildings adjoining with that charming individuality which invariably characterises this architect's work, but we cannot always admire his peculiar fancies, such as the wooden sashes in concrete or the sham windows at Holland Park, Kensington, and here at Chelsea we note flat brick arches without any skew-backs, and massively treated bay windows running up, say, three floors of the front, carried on iron columns of such small scantling as to be anything but satisfactory to the eye, notwithstanding the assurance of their ample strength to do their work. A concealed iron girder, following the shape of the bay, is tailed into the wall of the front, and helps to support the weight. There is probably no chance of failure, but the moulded brickwork encases the girder, and the small columns look uncommonly weak.

MR. JAMES CASSIE, R.S.A., died in Edinburgh on Sunday last. He was a native of Aberdeenshire, but has resided in Edinburgh about ten years. He was elected an associate of the Royal Scottish Academy in 1869, and an academician in February last. In the earlier period of his professional career he devoted much of his time to portrait and animal painting, but latterly his attention was given chiefly to landscapes, sea pieces, and river scenes. He was an intimate friend of the late John Phillip, a portrait of whom was one of the best he ever produced. Among his principal works are "The Mussel

Gatherers," "The Mouth of the Mersey," and "The Sea Breaking on a Lee Shore at North Berwick." Seven of his pictures were in this year's exhibition of the Royal Scottish Academy. The deceased was about 60 years of age and unmarried.

MR. W. B. RICHMOND, whose works in the Grosvenor Gallery this year have attracted much notice and admiration, has been appointed by the electors to the Slade Professorship of Fine Arts at Oxford, in succession to Mr. Ruskin. The other candidates were Messrs. Comyns Carr, St. John Tyrwhitt, J. Brett, Watkiss Lloyd, Cave Thomas and J. P. Seddon. The appointment is for three years, at the end of which time the Professor may be re-elected. In losing Mr. Ruskin the University has lost a princely benefactor, the munificent contributor to its art collection, and the creator of its Art School, in connection with which he founded and endowed a teachership of drawing, and presented from his own collection an admirable educational series of drawings for the benefit of the many pupils under the tuition of the present teacher, Mr. Macdonald.

WE referred last week, on p. 525, to the censure passed by "An Architect" in the *Cambridge Chronicle*, on the authorities of Jesus College, Cambridge, for allowing the screens, stalls, and other carved woodwork, placed in the College chapel by Bishop Aleock, to be turned out of Landbeach Church and offered for sale in London without making an attempt to secure and replace it. Mr. W. M. Fawcett, M.A., F.R.I.B.A., of Cambridge, has replied, explaining that the Fellows of Jesus College made an unsuccessful attempt years ago to repurchase the fittings, and a short time since the Dean offered to buy them at the sum Messrs. Kett, carvers, of Cambridge, might regard as a fair value. The offer was declined, and Mr. Fawcett expresses his annoyance at the charge of meanness which has been publicly brought against the College authorities. It is clear, however, that those charged with the pecuniary responsibilities of Landbeach Church restoration think they can get a higher price in London than from the Dean and Fellows of the College, and however much their mercenary spirit is to be regretted, they have an indefeasible right, apart from all sentimental and historical considerations, to haggle with the highest bidder for the carvings the parishioners of Landbeach bought and paid for a century since. Expressions of protest or regret will but tend to advertise the old properties and raise their value.

OWING to the fall, three months since, of a cantilever from beneath the cornice of the Town Hall at Ipswich, unfortunately killing a young man who was passing at the time, the Town Council of Ipswich accepted a tender from Messrs. Bennett for surrounding the building with massive scaffolding, and executing the repairs immediately necessary, at the same time instructing the borough surveyor, Mr. E. Buckham, and Mr. Frederick Barnes, F.R.I.B.A., of the same town, to make a careful examination of the building. They report that the cantilevers, mouldings, and panels under the principal

cornice, executed in Bath stone, are in many places cracked, and in some broken off. The stone has been pieced and patched, and fastened with iron cramps and wooden pegs. The principal cornice is in two thickness of Portland stone instead of one (as is also the coping of balustrade), the joints are laid in mortar of inferior quality and unnecessary thickness, the terminals are insecure, and the joints of the stonework in the dome are defective. They recommend that all the Bath stone be taken out and replaced with Portland, that the cornice be redressed, the defective joints in dome pointed, and the whole of the masonry coated with a solution of silica. This report was considered by the Corporation on Wednesday week, when the revelations gave rise to some discussion. One member, Alderman George Mason, declared that it must be patent to anyone who examined the building that the surveyors had not overstated the matter when they said that it was from bad materials and bad workmanship that the whole of this expenditure was rendered necessary. Stones were used which never ought to have been used; stones were used which were broken either in working the stones before they were put in, while they were being put in, or afterwards. They were fastened with iron clamps and plastered over the face; the action of the atmosphere had removed the plaster and exposed the whole cheat, for it was nothing else. It was a discredit to everyone concerned with it. In the end the report was adopted. The Town Hall is a large building of Florid Venetian character. It was erected a dozen years since from the designs of Messrs. Bellamy and Hardy, of Lincoln, by contract, by the late Mr. Gibbons, of Ipswich, and at the time the late Mr. E. C. Ribbans, then borough surveyor, and a man of great experience in building, was appointed over the clerk of works, at a salary, to supervise the work.

A REPORT has been presented to the Metropolitan Board of Works with reference to the electric light on the Embankment, in which the reporters, Sir J. Bazalgette and Mr. T. W. Keates, state that careful experiments have demonstrated that an engine of 10 nominal horse-power would drive the machines required. During each night of 5½ hours, however, 498½ lb. of Welsh coal were consumed, so that an approximate estimate of what is a "nominal" horse-power in this case may be made. The lights cost for motive power, attendance, &c., 3.24d. per hour each, to which must be added the cost of the "candles." In the opinion of the reporters there is no prospect at present of the electric light competing with gas for general purposes.

SALFORD.—The Salford School Board recently invited competitive designs for new schools about to be erected in Marlborough-street, Salford. Five plans were submitted which have been on view this week. On Wednesday the Board selected the plans sent in by Mr. Lord, and appointed him architect of the building. A premium of £25 was awarded to Mr. J. Lowe for his designs, which were considered as second in order of merit, and Messrs. Smith and Heathcote received £15 for plans submitted by them, which were placed third.

CHAPPUIS' PATENTS

FOR

REFLECTING LIGHT.—DAYLIGHT REFLECTORS

OF EVERY DESCRIPTION; ALSO

ARTIFICIAL LIGHT REFLECTORS.

P. E. CHAPPUIS, Patentee. Factory, 69, Fleet-street, London, E.C.

N.B.—DIAGRAMS AND PROSPECTUSES ON APPLICATION.

A LARGE number of different kinds of glass, good, bad, and middling, have recently been analysed by Herr R. Weber, in order to determine whether any, and what, relation exists between the chemical composition of a glass, and its power of resisting atmospheric influences. It appeared from this inquiry (described in the *Annales der Physik*), that neither the absolute, often considerable, quantity of silicic acid, nor an absolutely small quantity of alkali, produces good quality of glass, but that, besides the correct proportion of the quantities of silicic acid and bases (lime and alkali), the ratio of the quantities of the latter to each other had a specially determinant influence. The composition of many proved lime-alkali glasses approximates the proportion of equivalents: 6SO_2 , 1CaO , $1\text{K}_2\text{O}$ (or $1\text{Na}_2\text{O}$); but good glasses may also contain a larger amount of alkali, if this (otherwise unfavourable) proportion be compensated by more than six equivalents of silicic acid. On the other hand, a less proportion of silicic acid is permissible where the lime is diminished relatively to the alkali. The influence of argillaceous earth, in glasses which contain a large proportion of it, on their resisting power, must be tested by further analysis.

THE announcement that the restorers of St. Alban's Cathedral have now got together the timbers for the nave roof has drawn forth another remonstrance from the Society for the Protection of Ancient Buildings, which now wants to know if the subscribers are prepared for the inevitable consequences the new roof brings with it. "Are they content that the ancient painted ceilings shall be removed or destroyed, victims of the uncouth monster they have created? One of these ceilings is rightly described in the papers of one local archaeological society as 'not to be surpassed in England for beauty or historical association.' They are all of the greatest value, and yet their destruction is certain if the scheme, which has so far succeeded to the entire satisfaction of its promoters, be allowed to progress. Has the last inevitable step yet been reached? May we not still draw back? Will not the subscribers, who have so freely given their money for the honour of the church, gladly give it up rather than buy with it such a loss? The projected roof is quite unnecessary, and while it will rob the church of a long-established characteristic, it can but very uncertainly revive its earlier appearance."

PENTON MEWSEY CHURCH, HANTS, a valuable example of fourteenth-century architecture, which has been carefully figured by Mr. G. E. Street in the second volume of "Weale's Papers on Architecture," is about to be pulled down, and the materials sold to the builder of the new church, which is to be built near the site of the present one. The Society for the Protection of Ancient Buildings, after using every effort in their power to preserve the old church, find that they can only do so by obtaining subscriptions to the amount of £330 from those who value this building in particular, and old buildings generally, in order to pay this sum to the builder in

lieu of the use of the materials of the old church. Subscriptions for this purpose will be received by Mr. William Morris, hon. secretary to the Society, at 9, Buckingham-street, Strand, W.C. All subscriptions so received will be returned unless a sufficient sum is obtained for the purpose, and unless an undertaking is given that the old building shall be kept in proper repair by those who are now responsible for its custody.

THE Leadenhall Market Select Committee of the House of Commons, presided over by Lord Henry Lennox, concluded its labours on Wednesday. The market, which consists of an area of only 3,900 square feet, has belonged to the Corporation for more than two centuries, but around it a much larger market has sprung up. The Bill takes very wide and extensive powers, and one of the principal objections to it was that the whole of the land between Leadenhall-street, Lime-street, Fenchurch-street, and Gracechurch-street was scheduled, and there were no plans showing where the new market is to be constructed. The promoters, however, introduced one clause which provides that the old market shall not be abolished until the new one is ready to be opened. The present suggested site for the reconstruction of the market is along the whole of Half-moon-passage, leading out of Gracechurch-street, and part of Leadenhall-passage. The Committee passed the preamble of the Bill on the condition that the Corporation should construct a new market of not less area than 25,000ft.

DR. SIEMENS, the well-known electrician, has munificently offered the Council of the Iron and Steel Institute £10,000 as the nucleus of a fund for the provision of a suitable house for the societies representing the applied sciences. The members of these associations as a rule move more quickly in such matters than their literary and artistic brethren, and it is probable that the money will be subscribed and the premises erected long before a similar house for the learned societies which has been talked of for so many years, and designs and suggestions for which have been furnished by the dozen, has become anything more than a project. A committee has been appointed by the Iron and Steel Institute to consider the matter, and probably as soon as a site has been selected, plans will be invited.

THE annual Conference of the Society of Arts on water supply, sewage, and health was opened yesterday, and will be continued to-day (Friday). In the absence through indisposition of the Right Hon. James Stansfeld, M.P., Lord Alfred Churchill occupied the chair. The report of the judges upon the essays on water supply, sent in to compete for the medals offered by the society, was laid before the Conference yesterday, and the award announced of a silver medal to Mr. Frederick Topliss, and a second silver medal to Mr. Joseph Lucas for their papers. The papers and discussions are being taken under the following heads:—1. Methods of securing a sufficient supply of pure water. 2. Evils of impurity, and consequent connection

of the water supply and sewage. 3. Methods of sewerage, &c. Amongst the readers of papers are Prof. Hull, F.R.S. (Water Supply of the Eastern Counties), Sir H. Cole, Mr. Edwin Chadwick, Dr. Thorne Thorne (The Recent Fever Outbreak at Caterham), Archdeacon Denison (Water Supply at East Brent), Mr. A. H. Brown, M.P. (Rating for Sanitary Purposes), Mr. Ernest Hart (Connection between Disease and Impure Water), Mr. Cresswell (The Sanitary Condition of the Thames), Mr. J. Clarke Hawkshaw, Mr. Bailey Denton, Prof. Anstead, F.R.S., Mr. De Rance, Mr. Joseph Lucas, Rev. E. C. Clutterbuck, Mr. J. Lynam, Mr. James Dillon, Mr. Baldwin Latham, &c. An exhibition of mechanical and chemical apparatus, relating to water supply, treatment of sewage and health, is being held at the society's rooms during the conference. We shall deal more fully with the proceedings of the conference next week.

THE select committee of the House of Commons appointed to inquire into the Tower high-level bridge bill, the object of which is to construct a bridge over the Thames at the Tower, assembled yesterday. The scheme is submitted by the Metropolitan Board of Works for the construction of a high-level bridge across the river, below the Tower, and consequently below London-bridge. It was pointed out that about one-third of the population of London lived east of London-bridge, and had contributed at one time and another towards the freeing of several bridges west of London-bridge. Under these circumstances he did not consider that the pressure which had been put upon the Board of Works to afford to this third of the population of London additional bridge accommodation, which was greatly needed, was in any way unreasonable. It was admitted that the scheme was not altogether free from difficulties, and that some slight inconvenience would be caused to the home vessels that wished to go beyond the bridge, but he urged that such a great public benefit as this should not be stopped for such a small reason. The only inconvenience would be that some of the vessels would have to strike their topmasts coming up the river. Mr. E. N. Buxton, of the firm of Truman, Hanbury, and Buxton, was then examined in favour of the bill, and the committee adjourned.

CHIPS.

The three-light west window in Redruth parish church has just been filled with stained glass, as a memorial. The subjects are St. John, with chalice, St. Peter, with keys, and St. Paul, with sword and book.

The statue erected by the town of Cardiff to the late Marquis of Bute, and which for over twenty years has occupied a very prominent position in High-street, is about to be removed on account of tramway extensions, to a triangular piece of ground between St. Mary-street, Penarth-street, and New Station-road. The height of the monument will be increased by adding three circular stone steps beneath the pedestal of the statue.

Roofing Felts.—F. Braby & Co.

INODOROUS, SARKING, SHEATHING, AND HAIR FELTS KEPT ALWAYS IN STOCK. MANUFACTURERS OF PERFORATED ZINC, PERFORATED COPPER, AND PERFORATED IRON IN VARIOUS DESIGNS AND GAUGES.

Wrought Iron Tanks.—F. Braby & Co.

PAINTED AND GALVANISED, OF IMPROVED MANUFACTURE

Corrugated Iron.—F. Braby & Co.

GALVANISED AND BLACK IN ALL GAUGES, KEPT IN STOCK. ZINC WORK OF ALL KINDS.

FITZROY WORKS, 356 TO 369, EUSTON ROAD, LONDON.
HATTON GARDEN, LIVERPOOL. GREAT CLYDE STREET, GLASGOW. AND AT CYPRUS.

At Brighton, on Thursday in last week, Colonel Ponsonby Cox, local government board inspector, held an inquiry, which proved purely formal, as to an application from the Corporation for leave to borrow £5,000 for sewerage purposes.

The Local Board of Wirksworth have adopted plans by Messrs. Coke and Mills, engineers, of Chesterfield, for high and low pressure supplies of water to the town of Wirksworth, and to the hamlets of Bolehill, Steeple-grange, Gorse-bank, and Miller's-green. The estimated cost is £3,550.

The Derby Town Council has stultified itself by abandoning, on account of the expense, the scheme propounded under the Artisans Dwellings Improvement Act, and previously adopted. The Local Government Board have sent a sharp missive to the corporation asking for the reasons of the abandonment after the Board had taken the necessary steps for getting a special Act for Derby.

The hall at Barrow-on-Trent has just been decorated by Mr. Cantrell, of Derby, and the pleasure grounds have been laid out by Messrs. John Frettingham and Son, of Derby and Nottingham.

The new Catholic church of St. Joseph, in Elm-grove, Brighton, was opened for worship on the 8th inst. Only the nave has at present been erected. The architect is Mr. Broder, brother of the priest-in-charge.

The contract for the new roofs and bridges required for the improvement of Westland-row Terminus and the widening of the line has been given by the directors of the Dublin and Wicklow Railway Company to Messrs. Courtney, Stephens, and Bailey, of Dublin. The amount is about £13,000.

The corner stone of the new aisle of Christ church, Lowestoft, was laid on Saturday. The extension will provide 140 additional sittings, and is being built from the designs of Mr. W. O. Chambers, of Lowestoft.

The Oswaldthistle local board have referred to a recommendation of the desirability or otherwise adopting the Salford pail system of closets in the township.

The promoters of Selwyn College are about to purchase, for £6,050, 84 acres of land near the Newnham College and the Parallelogram-road, Cambridge, as a site for the proposed college.

The fine old parish church of Shifnal, which contains specimens of all kinds of architecture, from Norman to Late Perpendicular, is about to be further restored, at a cost of £1,000. The work of restoration was commenced under the late Sir Gilbert Scott in 1876.

The monthly meeting of the Bedfordshire Architectural and Archaeological Society was held on the 8th inst. It was announced that Mr. Ransom had completed a description of the church bells of the county, and that the MSS. had been placed in the hands of Mr. T. North, F.S.A., for publication. It was arranged to have an archaeological excursion to Leicester on Tuesday, July 15th.

A new cattle market was opened at Clitheroe on Monday. The cost has been £2,000. The market has been erected from the plans and under the direction of Mr. John Hargreaves, the Borough surveyor.

Last week, in our description of the Yorkshire Fine Art Industrial Exhibition, we omitted to mention that the greater part of the glazing (over the picture saloons, &c.), consisting of 14,000 superficial feet, was done on Rendle's patent system.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Society of Arts. Cantor Lectures, "Recent Advances in Telegraphy," by W. H. Preece. Lecture V., "Automatic and Fast-speed Telegraphy," 8 p.m.
Royal Institute of British Architects. 8 p.m.

TUESDAY.—Society of Arts. Special Meeting. The adjourned Discussion on W. Lloyd Wise's paper on "The Government Patent Bill" will be resumed, 8 p.m.

WEDNESDAY.—Society of Arts. "Edison's New Telephone," by Conrad W. Cooke. Prof. J. Tyndall, L.L.D., F.R.S., will preside, 8 p.m.

British Archaeological Association. Papers on "The Bronze Gates of Ballinavat," by T. Pinches; on "Sculptured Stone in Ely Cathedral," by W. De Grey Birch; and on "Antiquarian Losses in Coventry During a Century and a Half," by W. G. Futton, 8 p.m.

THURSDAY.—Society of Arts. "The History of Alizarine and Allied Colouring Matters, and their Production from Coal Tar," by W. H. Perkin, F.R.S. Part II., 8 p.m.

FRIDAY.—Indian Section. "The Harbour of Karachi," by W. J. Price, M.I.C.E., 8 p.m.
Architectural Association. Paper by W. Penstone on "Late Iron-work," 7:30 p.m.

Royal Institution. W. H. Preece on "Multiple Telegraphy," 9 p.m.

HELLIWELL'S Patented NEW SYSTEM

IMPERISHABLE GLAZING WITHOUT PUTTY.
All Woodwork is covered, and no outside Painting is required. Old Roofs Re-glazed. Any one can repair or take in pieces.

See half-page Advt. in next Number.

T. W. HELLIWELL, Brighouse, Yorkshire;
or, 19, Parliament-street, London.—[ADVT.]

Holloway's Pills and Ointment present the readiest and most reasonable means of removing hereditary, constitutional, and chronic disorders associated with impure blood and unhealthy skin. Scurvy, scorbutic affections, unseemly eruptions, enlarged glands, and other blemishes yield to these purifying remedies which eradicate the seeds of the complaint and avert mischief.

Trade News.

WAGES MOVEMENT.

BLACKBURN.—The flaggers and slaters are acting in concert, and the effect will be to stop bricksetters, plumbers, glaziers, joiners, carpenters, and all others engaged in the building trades. The masons, flaggers, and slaters have adopted the picketing system. The masons say that wages in Blackburn are considerably under those of other towns—Bolton, Preston, and Manchester. The masters say that the reduction is supported by public opinion.

BLACKBURN.—The stonemasons of this town, numbering about 350, recently received notice of a reduction of 3s. per week in wages, to come into effect on Saturday last. A meeting of the men was held last week, under the presidency of Mr. Alexander Wilson, at which it was decided to come out on strike on Monday for a period of at least three weeks.

CARLISLE.—The joiners of this city have agreed to accept a reduction of ½d. per hour, the working hours to remain the same as before.

DARWEN.—The painters are on strike in consequence of the masters enforcing a reduction of ½d. per hour at one month's notice. The operatives have published a statement that they gave three months' notice when they applied for an increase, and that they expect, in justice, to be afforded a similar time.

HASLINGDEN.—On Monday the quarrymen in the employ of Mr. Thomas Hargreaves came out on strike rather than accept a reduction of 5 per cent. in their wages. They allege that a previous reduction of 15 per cent. having been made, the present reduction is against the decision arrived at that their wages should not again be lowered.

WARRINGTON.—The employers and men in the various building trades, recognising the depressed state of trade, have come to an amicable arrangement for a reduction of wages.

WEST BROMWICH.—A largely-attended conference of operative builders of West Bromwich, Oldbury, Smethwick, and Wednesbury was held on Wednesday week at West Bromwich. The chairman, Mr. Henry Badham, said the object of the meeting was to consider the result of the meeting of the employers and the delegates of the operatives with reference to the proposed new code of rules on the government of the trade. He regretted that the masters had not only declined to entertain the question of the rate of wages paid prior to February last, viz., 7½d. per hour—but had refused the compromise offered by the operatives of 7½d. Had the men been more united they would not have been in their present position, and he urged them to join the union, and so be prepared to resist any further reduction which might be proposed. After some discussion it was agreed that the question of wages stand over, pending the completion of the amalgamation of the Oldbury operatives with those in the trades' union of West Bromwich.

Doubling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to

CHARLES TRASK,

Norton-sub-Hamdon, Ilminster, Somerset.

Agent: Mr. E. CRICKMAY, 4, Agar-street, London, W.C.
—[ADVT.]

TENDERS.

ARNOLD.—For lodge, Cherry-hill, Arnold. Mr. Robert C. Clarke, architect:—
Smith and Greaves £275 0 0
Wyate, A. (accepted) 275 0 0

ARNOLD.—For organ chamber, St. Ann's Church. Mr. Robert C. Clarke, architect:—
Sleepstone, Wm. £160 0 0
Vicker's Henry 155 0 0

CARLTON.—For dwelling-house, Carlton, near Nottingham. Mr. Robert C. Clarke, architect:—
Vickers, Henry £630 0 0
Hey (accepted) 595 0 0

J. & E. HALL

(ESTABLISHED 1785),

ENGINEERS, MILLWRIGHTS,

FOUNDERS, AND BOILER MAKERS,

Works:—DARTFORD, KENT.

London Offices—21, St. Swithin's-lane, E.C.

Sole Makers of MOTTE'S

UNIVERSAL CRUSHER.

THE SIMPLE PESTLE AND MORTAR ADAPTED AS A MACHINE.

Hand and power Machines with Mortars, of from 6in. to 30in. diameter.

These Crushers are the most effective and economical Machines known for reducing the hardest materials, as Emery, Granite, Quartz, Glass, Flint, Cement clinkers, Pyrites, and the like, from any size down to the finest powder.

They will also be found very useful in a Laboratory for grinding, bruising, or mixing drugs and colours of every description. The facility with which these Machines are regulated to deliver the ground material, now at one size and then at another, forms one of its chief attractions.

PRICES AND ALL PARTICULARS UPON APPLICATION.

HART'S PATENT

CYCLIC ELEVATOR.

For which see Advertisement each alternate insertion.

EDGB-RUNNER MORTAR MILLS,
In specially hard Cast Iron, outlasting several of the ordinary description.

ESTIMATES FURNISHED FOR

CEMENT & BRICKWORKS MACHINERY.

Complete with the latest improvements, together with the best practice for laying out the works for strict economy.

ENGINEERS, BOILERS, CASTINGS, AND ENGINEERS' WORK IN GENERAL.

THE BUILDING NEWS.

LONDON, FRIDAY, MAY 23, 1879.

ARUNDEL CHURCH AND THE DUKE OF NORFOLK.

A CASE of more than usual interest to architects, and especially to those of them engaged in ecclesiastical work, has just been decided before Lord Chief Justice Coleridge, in the Common Pleas Division. We refer to the action brought by the Duke of Norfolk against the Rev. George Arbuthnot, Vicar of Arundel, for trespass, in breaking down a wall which had been built by the Duke to divide the chancel of the church, called by the Howards the Fitzalan Chapel, from the rest of the edifice. His lordship, having taken time to consider, pronounced, on Saturday last, in favour of the Duke of Norfolk on all issues. It may be recollected that the Duke claimed absolute property in the so-called "chapel," which was contended belonged to the original college and not to the parish church of St. Nicholas, and attempted to restrain the vicar from further trespass; on the other hand, the vicar, in his defence, set up a claim to the chancel as being an integral part of the church, praying for an injunction to restrain the Duke from obstructing the right of the parish to light and air by building the wall in question. As the issues of the case are so closely connected with the architectural integrity of the building; and as one of the leading ecclesiastical architects of our day, Mr. Butterfield, was called in support of the defence, it may be of interest to examine a little more minutely than has been done by our daily contemporaries the evidence on both sides. We may at once confess the case is one of those where legal right is stronger than the inherent equitable and moral elements involved, and in reading the elaborate written judgment of Lord Coleridge, we are constrained to say, the architectural unity of the church, so ably supported by Mr. Butterfield, has not had a fair consideration. The evidence upon which Lord Coleridge based his judgment was clearly the acts of ownership on the part of the Dukes of Norfolk. For example, instances were given of interment in the chapel without a faculty, the disinterment of bodies at the free will of the Duke's ancestors; the fastenings of the iron gates in the chancel screen, which separated this part from the rest of the edifice being on their eastern side, and the key having been kept from time immemorial by the dukes or their stewards; strangers had been excluded since the Reformation, and even the neglect and mutilation of the chapel itself was brought forward as one of the strongest proofs of ownership. It was contended that this state of dirt and neglect had been allowed to remain without remonstrance, and that admission which for three centuries was denied to the parishioners had been granted to bats and owls. His lordship, rather needlessly under the circumstances, pointed to the Protestant persecution of the religious belief of the family as some ground for this strange conduct and for the neglect into which this charming building had fallen. Speaking of the evidence for the defence, his lordship said that there was nothing to prove services had been held in the so-called Fitzalan chapel, while the churchwarden's report at episcopal visitations upon the state of the "chancel," then in the transept, were usually that it was "good" or in "excellent repair" at the time the chancel, as the defendant considers it, was in a ruinous state. It will be admitted this view of the case was a little disingenuous.

It did not take into account the ultra-Protestant bias of the time, the ignorance of what constituted a chancel, nor the average intellect of a churchwarden in ecclesiastical matters, nor the over-bearing temper of an English squire of the last two centuries. Referring to Mr. Butterfield's evidence, we contend the conclusions drawn by his lordship appear unsatisfactory. The cases cited as showing that an integral part of a sacred edifice could be vested in a private person scarcely meet the architectural facts which we shall presently refer to, that the building in question is part of the parish church, and that the rights of the priory or college of Arundel, as rector, might have been served equally in such a case. Here was, to even an ordinary eye, a distinctly evident chancel, divided by a screen of unusual openness from the rest of the building, and the decision of Lord Coleridge virtually sets aside a patent fact as irrelevant. So far, then, the judgment given has mainly rested upon acts of ownership proved, and not at all upon the architectural unity of the building; and we have a precedent set of a certainly very unfortunate kind in the interests of architecture.

In reading Lord Coleridge's judgment it would appear things were thrown in to give weight which really were of trifling moment to the real issue. Thus, with regard to the Ten Commandments, their position was misunderstood by his Lordship. In the churches round Arundel, as in all the earlier specimens, the Commandments are, as intended by the Canon, over or round the chancel arch, and at Arundel Church they are still legible in this position, proving it to be, therefore, a chancel arch; but placed in the eastern wall of chancel 80ft. distant they would have been unreadable. Indeed, before the time of Sir C. Wren, who did not build chancels, they were not a customary adornment of the altar-piece. Again, Lord Coleridge, as evidence in the Duke's favour, referred to the entire filling-up with iron lattice of the chancel arch above the screen as unique. In principle, we think this treatment makes the other way, for in the case of most wooden chancel screens the arch would have been filled up solidly, and not, as at Arundel, transparently. The brick wall erection had, too, a far larger meaning than one of light and air; it includes chiefly the question of sound, and helped the Duke, by thoroughly separating the chancel from the nave, to make the former a separate building, suitable for a second congregation, and the worship of a separate communion. The whole value of the chancel is thus altered enormously to the Duke; but certainly "user" cannot be pleaded for this brick wall. Hitherto, everything going on in the nave could be heard in the chancel. This is no longer the case. Again, a point was made of churchwardens' answers; but any one acquainted with them knows how little reliance can be placed upon them, and how ridiculous they often are living archdeacons can testify.

As a distinct architectural issue was first contemplated by the Duke's advisers, namely, that the so-called chapel was a separate building, and not the chancel to the parish church, it may be interesting to give a brief description of the church of Arundel, illustrated in the BUILDING NEWS, p. 146, Vol. XXVII. It is a fine cruciform building, with short transepts, and with a square central tower. The Fitzalan Chapel, as it is called by the plaintiff, extends eastwards as a long, lofty chancel of collegiate character. Between the eastern tower piers an open screen of iron with wide gates exist. On the north side is a large aisle, dedicated as the Lady chapel, with a vestry at its east end, the character of the building is Perpendicular, and it is assigned by Mr. Butterfield to belong to the end of the 14th century. Mr. C. Bowen, in his reply for the Duke, referred to Mr. Freeman's remarks on old

monastic and collegiate churches when connected with parish churches, and assumed without foundation that what was true of monastic and parochial churches was equally true of collegiate and parochial churches. The parish church, formerly monastic and parochial, was rebuilt at the end of the 14th century, as we now see it. The Earl of Arundel, its founder, placed in it a master and a body of chaplains. The property was surrendered by the college December 12th, 1541, to Henry VIII., and was granted on the 26th of the same month to Henry Fitzalan, Earl of Arundel, the last of the Fitzalans. The Howards, who had intermarried, followed them. As regards the term "Fitzalan Chapel," it could not be proved at the trial that the name has any authority, but has been merely invented of late years with a view to making the chancel appear a private family possession. Since the dissolution of the College in the 16th century, the chancel has not been used for service, except the Burial Service of the Church of England; it has always been open to view from the nave, through the original open iron screen in the chancel arch, and has been accessible from the nave for funerals and visitors, by means of its old iron folding-gates therein. These gates and screen still remain. This chancel was described in a letter to the present Bishop of Chichester as being, thirty years ago, in a state of great desolation. Even the costly tombs of the Howards lie in ruin, and so neglected has the chancel become, though claimed as private property by the family, that the idea of its being a part of the parochial fabric has been, as far as could be, weakened in the minds of the parishioners. The conduct of the parishioners, who are also the Duke's tenants, must not, therefore, be judged too harshly. It has been a standing offence; so that the solid building-up by the plaintiff of the chancel-arch in 1873 was only too likely to be acceptable to many of the parishioners, on the mere score of comfort. A quotation from Tierney's "History of Arundel" tells a pitiful story of mischief done by persons employed by Charles, Duke of Norfolk, in 1782. He says they stripped the building of its lead, demolished the parapet, took down the entire roof, which was magnificently groined, and allowed the timbers to fall at random. Beam after beam fell, the stalls were crushed, the tombs were shattered, and the floor broken in. Great stress is laid on what was "commonly called" the "parish chancel" and "parish altar" in the south transept. There is great weight in the argument that the chancel altar was used by the parishioners, who could not avoid distinctly seeing it from the nave at all times, though no doubt small congregations often used the altar in the south transept whenever there would be inconvenience in their using the chancel altar. The latter, of course, being behind the great tower pier, was invisible to the mass of worshippers. Further, the position of the ancient stone pulpit built into the same pier of the tower is another strong point to prove that the building claimed as the chancel is such. This, the parochial pulpit, has its back to what the plaintiff would wish us to accept as the "parochial altar." Hence the pulpit is clearly proved to be in the right relationship to the chancel and its altar. The unusual architectural dignity of the pulpit is undoubtedly important in establishing the unity of the chancel and nave. It would be every way incongruous if the building claimed as chancel were not an integral part of the church. Many quotations can be given to show that the term "chancel" is used, and that the two parts form, in fact, one building; but we cannot devote further space to this point, nor is it necessary now that the integrity of the two have been conceded to the defendant. The case in course of the

trial shifted its ground from the position first taken by the plaintiff, who in the beginning wholly denied the name of chancel, and was concluded on quite another issue. No one with any architectural knowledge of churches could have mistaken the chancel for anything else, and Mr. Butterfield proved demonstrably that the several features of chancel, altar, arch, screen, rood-loft and pulpit must be taken together. The argument of the plaintiff, that the chancel is only a private chapel and not part of an inseparable whole, so absolutely failed that Lord Coleridge disallowed it. The issue has important architectural bearings, and although the evidence adduced by Mr. Butterfield has been set aside, we consider the Duke's position is morally considerably weakened by this trial. It may be mentioned that the architectural evidence was at first much relied upon by the plaintiffs, but the difficulty they found, on applying to architects, in obtaining concurrence in this view induced them to abandon this aid altogether. Thus it is well known that Mr. Butterfield was first asked to act on the plaintiff's behalf, failing which, another eminent ecclesiastical architect was applied to; but after visiting the church he too declined to appear as a witness for the Duke. It has at least been proved to every one conversant with ecclesiastical buildings that what has been, and is still, claimed as a private chapel is absolutely the chancel of Arundel parish church, that it was used as such before the Reformation, and that its after-separation and neglect was due to the general apathy and disturbed condition of the times, and to the overwhelming power which the Dukes of Norfolk, as owners of the whole property of Arundel, have possessed. On another ground, that of right and moral feeling, the decision of Lord Coleridge is even more deeply to be deplored. It will be an unfortunate precedent to those who have vested interests in buildings of this class, though it is equally true our squires have been doing all over England just what the Duke has done for centuries past, and that getting faculties twenty-five years ago was a most rare thing. It is much to be lamented that so beautiful an example of Mediæval architecture should remain in its present condition as a neglected chancel-house of the Howards, instead of being made worthy of the Church to which it has for centuries belonged.

THE NATIONAL PORTRAIT GALLERY.

ONE of the most instructive as well as valuable collections of pictures to be seen at South Kensington, is the National Portrait Gallery located in the old Exhibition galleries in the Exhibition-road, opposite the Science Schools. Though admittedly the building is a makeshift unworthy as the receptacle of such a national display, we find considerable alterations have been made to it of late, and the exhibition, after having been closed, is shortly to be reopened to the public. It may be mentioned that the present galleries formed a part of the Exhibition building of 1862; they were never designed nor intended for pictures, and, we may observe, are constructed in a rather rough and temporary manner, and we cannot indeed, while speaking of the building, omit to say the present magnificent collection of portraits is not so safely housed as we could desire to see. One of the upper galleries is over a sort of mezzanine story, now used as a store, and is often much heated by gas; the floors we find are not fire resisting, and we fear to contemplate such a risk as an outbreak of fire.

The rearrangement that has been made under the direction of Mr. George Scharf is in every way an improvement; the two long galleries to afford the necessary room for the newly-acquired portraits are divided into

bays by screens on the window side, allowing ample passage-way on the other. In the former arrangement the screens were too close, but the present allow a very fair light, besides facilitating the division of the subject into periods. We think also for the purpose of the student and connoisseur this breaking up of a long gallery into bays is a desirable one, as it favours quiet study, and lessens the monotony and tedium inseparable from a long gallery of pictures. In addition to the galleries we see that the old naval room, used formerly for models, has been converted into a large well-lighted compartment by the closing up of the series of windows, and by the introduction of skylights in the slope of the flat timber roof. Commencing at this gallery, we notice an important acquisition of portraits has been made. The trustees of the British Museum have transferred a large collection of very valuable oil portraits, which hitherto has been consigned to one of the dingy and neglected courts of the national treasure-house in Russell-street. Among the collection that Mr. Scharf has arranged with so much skill and appreciation are to be seen a portrait of Craumer in excellent preservation, shewing the great Reformer in his prime; Queen Elizabeth, painted by Zuccheri, is another excellent example, and to show the accumulation of dirt upon it the picture has been half-cleaned. A full-length portrait of the Prince Consort is hung at the end of the room, and we note a marble bust, by Armstead, of Earl Stanhope, the founder of this gallery. Another even more valuable presentation to the national portraits was made in 1877 by the Hon. Society of Judges and Serjeants of Serjeants' Inn, comprising portraits of eminent judges, from Lord Chief Justice Coke, the liberal and independent lawyer of Charles I.'s time, to Lord Denman—a series of great lawyers, of much interest. Descending to the gallery on the first floor, we commence with the Plantagenets, ending 1485, after which are the Tudors. In this epoch we find portraits of Elizabeth and her envied rival, Mary Stuart, Queen of Scots, and her son, afterwards James I., painted as a boy. In the tablet beneath the former it is stated the portrait was painted by Oudry in 1578, during Mary's imprisonment at Sheffield. The portraits during the Stuart period, 1603 to 1714, comprise some remarkable men. Conspicuous in this department is the well-known Chandos portrait of Shakspeare, and King James I., being a full-length seated figure. We also notice a painting of Ben Jonson. The Commonwealth is represented by an excellent portrait of Oliver Cromwell by an unknown painter, painted when Cromwell was 58, though he looks younger. The painting is said to be enlarged from a celebrated miniature in the possession of the Duke of Buccleuch. Another characteristic portrait is that of Thomas Hobbes, the philosopher, of Malmesbury, and the secretary of Bacon. We also note paintings of James Harrington, the well-known author of "Oceana," dressed in the deep collar of point lace and thick, long curling hair—certainly becoming—and having a somewhat dreamy expression; of E. Cocker, arithmetician; and of Edmund Waller, poet. An interesting collection of autographs form a part of the exhibition, and these have at present been arranged in frames by themselves. We notice an original letter, written by Edmund Burke to the Marchioness of Thormond, containing a draft of an introduction to a catalogue of ancient paintings formed by Sir Joshua and sold by Mr. Christie. It was printed for the sale. The letter was presented to the gallery by Mr. G. Scharf, F.S.A. Several portraits of stirring interest are to be found in the part representative of Charles II. For example, besides the portrait of the King and some of his courtiers, a complete series of his

mistresses adorn one screen. There is Louise de Querouaille, who became Duchess of Portsmouth; Nell Gwynn, painted by Sir Peter Lely—a skilfully-executed likeness of this popular courtesan, in blue and brown drapery; the Duchess of Cleveland, &c. Of celebrated men of the period we note Isaac Barrow, the theologian; Samuel Butler, Pepys, &c. The portrait of the Countess of Shrewsbury, by Lely, is a splendid example of portraiture, in the painter's best style, crisp and rich in colour, enclosed in an oval frame. We observed a fine three-quarter portrait of the Duke of Buckingham, the profligate courtier and companion of Charles II., by Lely; one of George Monck, Duke of Albemarle, the General of the Forces, and who defeated the Dutch fleets. The reigns of James II., William III., and Queen Anne are well illustrated by portraits of notabilities. We note a painting of the King, by Riley; another of Lord Chancellor Jeffreys, the cruel judge, painted when he was Recorder of London, by Kneller, though there is nothing in his countenance to indicate the merciless judge; one hand is badly drawn. William Lord Russell, implicated in the Rye House plot, is an excellent painting; while John Lord Cutts, warrior, is a youthful and handsome face, by Wissing. John Dryden, by Kneller, and portraits of Addison, Steele, John Locke, Somers and Congreve are here. Sir C. Wren, by Kneller, painted standing resting his hand on a table, upon which lies a plan of St. Paul's, is the original of a well-known engraving. We have little space to enumerate other portraits of celebrities of the reigns of the Georges. We note a portrait of Sir W. Chambers, painted by Sir Joshua Reynolds, and a capital painting of the great painter himself when a young man, looking at a picture, shading his eyes by his hand. Portraits of Garrick, Warren Hastings, James Barry, R.A., J. Watt, Sir W. Scott, Dr. Jenner, Jeremy Bentham, Sir T. Lawrence, T. Clarkson, the abolitionist of slave trade; Wordsworth, a full-length portrait of Cobden, presented by the Reform Club; John Lord Campbell, Wellington, by Count D'Orsay, and numerous others crowd upon the visitor in the lower gallery. In the present very scant notice of a few of the leading portraits, it has been impossible to say much of the merits from an art point of view of the productions, though the authorities seem to have secured in most instances authentic works by well-known painters of portraiture. The exhibition, we hear, is to be reopened on Whit Monday, when we have no doubt a large and intelligent crowd of visitors will inspect it. The collection ought to be regarded, indeed, as a supplementary aid to the study of our country's history, containing as it does the portraits of the leading actors in the historical drama of the last 600 years. No effort has been spared on the part of the authorities, while the arrangement—at present necessarily imperfect—must be admitted to be a success.

NATIONAL WATER SUPPLY, SEWAGE, AND HEALTH CONFERENCE.

ANOTHER annual conference has closed its labours in connection with the above subjects since we last went to press, but with what effect upon the mass of materials and details accumulated since last year it would be hazardous at the present moment to say. We may, however, assert that no previous sitting of the conference has so large and valuable an array of facts and evidence been brought to bear upon the two great questions that engaged the conference last Thursday and Friday. The papers and suggestions published by the Society of Arts have been of the most varied and useful character, not a few of them having been

contributed by the leading sanitary authorities of the day. The National Water Supply engaged the attention of the meeting the first day, and on another page will be found a report of the proceedings. Lord Alfred Churchill, Chairman of the Council, and Mr. Stansfeld, M.P., presided over the first day's conference, the business of which mainly consisted in the reading of papers, or, rather, the digests of essays to which the Council of the Society of Arts had awarded medals. These contained suggestions founded upon evidence already published, for dividing England and Wales into watershed districts for the supply of pure water to towns and villages; and from a perusal of those which have been premiated, it must be acknowledged the Society have elicited some very valuable hints for future guidance, although more or less crude and imperfect. As we give a summary of these in our report, it will be only necessary here to lay before the reader the leading points of these schemes, reserving our own conclusions with regard to them. We may, however, enunciate a preliminary proposition that seems to simplify the matter, and to reduce the number of really practicable schemes before us. It is the undoubted necessity in any present or tentative scheme of preserving, as far as can be done without the sacrifice of a general principle of action, the existing works for water supply, for a radical sweeping away of everything that has been done at great outlay, for perhaps an entirely new, untried, and imperfect scheme would be a decided national mistake. All the suggestions have one common principle in them—that is, a division of the country into districts, more or less coterminous with the watersheds; and it must be allowed that this is certainly the most scientific principle upon which to base any efficient plan. Existing boundaries for sanitary purposes are acknowledged on all hands to be both inefficient and uneconomical; they are entirely independent of all sanitary and hydro-geological considerations; they cut houses and urban districts in the most absurd manner, and give rise to endless complaints and costly litigation. Areas of unions are not certainly adapted for sanitary purposes, as we have more than once pointed out, as the smallness of the area necessitates imperfect local administration; while the Local Government Board have not the information and local knowledge available which is requisite. In the language of the Royal Sanitary Commission, local administration "should be simplified and strengthened." Mr. Toplis, the author of the first essay printed, proposes to map out the country into watershed districts, "each containing one or more river basins, and that a body of commissioners be appointed to each district; that these commissioners should be assisted by competent legal and engineering advisers, who should have charge of the rivers and waterworks in their district, and that they should have power to acquire all existing waterworks, and if necessary all canals." He further proposes a minister of health with an adequate staff, who should have control over the above commissioners and all sewage authorities and manufactories. The maps accompanying Mr. Toplis's paper propose to divide England and Wales into twelve districts, as follows: The North-West, the Welsh, the Severn (the largest), the South-West, the Southern, the South-East, the Thames, the Eastern Counties, the Lincolnshire, the Midland, the Yorkshire, and the North-Eastern districts. We cannot devote the space necessary to show how these are defined, and indeed without a map any description would be unintelligible; but we may generally observe that the author takes the lines of watersheds separating the great river basins. Mr. J. Lucas is the author of the second essay, the substance of

whose scheme is to make the watershed area the unit of administration for water supply, and that there should be three commissioners' districts and sub-districts formed. The North of England is made one district, the Midland Counties and Wales another, and the Southern a third, these being made on the principle that the rivers flow east and west, and the mountains and geological lines run north and south. By this arrangement each commissioner's district gets its full share of mountain, plain, and geological strata. Mr. Lucas also proposes, as others have done, the creation of Watershed Boards to deal with water-supply, subject to the control of the commissioners. The areas of these boards are arranged into thirty-six natural groups, each being related to the watershed basins contained in it, and which draw their supply from one source. The author refers to the advantages of his scheme, the chief which is the localisation of scientific knowledge and officials in each district, and the avoidance of red tape, the cause of so much friction in administration. A far bolder though impracticable scheme was described by Mr. J. C. Birkett, the author of another paper. It was no less than the collection of the rainfall of the hilly districts of Westmoreland and adjoining counties in reservoirs, and its conveyance by an aqueduct about 514ft. above Ordnance datum, southwards to other high reservoirs round the metropolis, besides distributing branches to towns and villages on its route.

In the discussions which followed these papers, it was conceded by most of the speakers that the watershed area was the proper unit. The remarks of Professor Ramsay forcibly dwelt upon the value of underground sources of supply, and he instanced the sandstone districts, where good water might be obtained if judiciously tapped; while Professor Symons contended for a comprehensive scheme instead of the reckless plan by which a wealthy town got a large supply at the cost of other communities, as in the instance of Manchester and the Thirlmere district. We quite concur in the suggestion that the question should be placed under the consideration of a Minister of Health, and that a central office for the collection of statistics is the first step to be taken. Professor Symons agreed with the former speaker that the Welsh water was as good as that from Cumberland, and he said there were only three of the lakes that were high enough for gravitation supply. On the whole, the evidence of the speakers was conclusive in showing the generally felt necessity for a redivision of areas, and the value of a survey of the underground sources of supply. Professor Ansted suggested the rivers as boundaries; and Mr. Lucas's ideas were endorsed as to the desirability of a hydrogeological survey, and the gauging of all rivers, though, as one speaker said, no hard and fast boundaries could be laid down for districts. Captain Douglas Galton's remarks really contained the substance of the morning's discussion, and, as he said, although there were differences of opinion as to these districts, there was a general consensus of opinion that the printed information we possess should be brought to a focus. Every sanitary official is aware that though there were departments that possessed the information, they were so scattered that time was wasted in practically bringing any fact to bear upon the wants of a district. Captain Galton's idea was to bring into official relation with the Local Government Board the Director-General of the Geological Survey, the Director of the Ordnance, and the Registrar-General's Departments.

On another question, the incidence of rating, Mr. A. H. Brown's paper dealt with a rather difficult matter in a justly comprehensive spirit. Everyone will admit that it is unfair to levy a rate equally upon all the

property in a certain area or parish, irrespective of the actual benefits conferred by water supply and drainage. In many villages some properties are only indirectly benefited, others not at all; and Mr. Brown's proposal is that when a house is drained the cost of the works should fall upon it. The principle that the water supplied by the sanitary authority should be paid for only by the consumer, and the drainage provided should be paid for by a fair charge on the house, is both equitable and just, though the resolution framed by Mr. Brown evidently did not meet all the cases, as, for example, the one forcibly put by Dr. Alcock, of Sunderland, nor that instanced by Mr. Stansfeld himself. It would not be fair, for instance, that the same rate should be levied on a house not directly benefited by a sewer, as that upon another property directly connected with it, though unquestionably the district as a whole is benefited by drainage, and therefore should contribute something; nor would it be just that the cost of construction of sanitary works should fall entirely on those who at the moment of building should want water. As at first worded, the resolution met with opposition, and ultimately, on the recommendation of the chairman, the meeting objected to commit itself to any resolution; and notwithstanding the sound principle inculcated by Mr. Brown, and the fact that the incidence of rating in rural districts demands readjustment, such a decision is in the present unsettled state of opinion prudent. Captain Galton's resolution for the formation of districts under local authorities for administering the water supply also fell through, and Lord Alfred Churchill's subsequent motion, pressing upon Government the necessity of immediate steps being taken to carry out the resolution of last year was carried, though we fear, in the present moribund state of the Government, it is rather hopeless to anticipate any action in the matter. We can only allude to some suggestive papers read by Mr. Lucas, on subterranean water ridges, and by Mr. James Dillon, on the effects of under and arterial drainage, to which we may refer again. Mr. Rawlinson's able remarks in the discussion which followed will check the unbounded faith of many in unlimited sources of underground supply. He showed that the waterless areas were much in excess of water-bearing areas, and that floods were caused by excess of water upon a super-saturated soil. We cannot go quite so far as to agree with him that land drainage had nothing to do with increasing floods.

Last Friday the evils of impurity were largely dwelt upon, the leading paper upon the subject being that read by Dr. Thorne Thorne, the purport of which will be found in our report. The two points that seemed to elicit most discussion were the minute quantity of the poison which gave rise to the outbreak of enteric fever at Caterham, and the opinion expressed that chemical analysis could not distinguish the poison germs—matters that ought not to be overlooked in the interests of future investigations, nor should the legal dictum quoted by Mr. C. N. Cresswell, in the Coker mouth case. Mr. Hart's observations and his summary of epidemics produced by polluted water supply, ably supported the now well recognised fact that epidemics of enteric fever are largely due to water pollution. The tabulated statement appended to Mr. Hart's paper, minutely states the source of supply as the exciting cause, and the circumstances of each epidemic from 1866 to the present day; again Mr. Baldwin Latham's comments were valuable as proving that outbreaks always occur after a dry period, and when the springs have been low, while the effects of irrigation and light in destroying the poisonous character of water, lead to the conclusion that underground pollutions are more destructive than those above ground. The resolution

proposed by Mr. E. Hart, dealt with the above dangers, and met in the only possible way the contamination of watercourses during their construction and repair. Sir Henry Cole urged a very important conclusion respecting sewage farming, namely, that the storm water should be kept out of the sewers, and that precipitation should take place before the sewage flowed on the land. Passing to Mr. Crosswell's interesting paper upon the abortive attempts made to get rid of sewage in the Thames Valley, the pollution of that river, and the recent cross purposes of the Conservators and the Board of Works were alluded to, and a resolution was agreed upon, urging on the Government the necessity of taking legislative measures to prevent the mischief. Captain Galton threw some light upon the adoption of the present sewage discharge, and showed, what we have before contended, that the present outfalls were decided upon in opposition to the opinions expressed by himself and other referees, that the outfalls should be carried below Crossness to Sea Reach, by which scheme one-third only of the sewage, instead of two-thirds, would have been pumped into the river. Captain Galton showed also that if the scheme of the referees had been adopted, the cost would have been considerably less than any alteration now attempted which would necessitate greater depth and the increase of pumping power. Mr. Latham's observations were certainly corroborative. We need not discuss the question of sewage farming. Colonel Jones's experiences at Wrexham prove the undoubted profit to be derived when suitable conditions exist, such as good land and the exclusion of storm water; and the only new feature we need remark upon was the introduction of a pneumatic ejector patented by Mr. Isaac Shone for the lifting of crude sewage by compressed air power. Our space forbids a detailed description of this appliance, though its simplicity of action seems to warrant the idea of its extended use. It is unnecessary to refer to other subjects brought before the conference, such as Mr. H. Master's double-check system of house-drainage—a plan we have before referred to, in which the principle of disconnection is carried out; or to Mr. Banner's well-known system of house sanitation—the demonstrations given of which rather perhaps weakened the value some attach to the cowl as a means of promoting the up-current in the pipe. On the question of the pail system and its cost at Rochdale, the inquiries made tend to show that this system of disposal was still a favourite one in rural districts without a convenient outfall, and that it was gradually superseding the midden. As the chairman said in his summing-up, it dealt with the question of disposal at its source, and avoided all danger from sewer gases; on the other hand, it appears to be rather costly; even the Rochdale authorities were not prepared to give the real cost of the system per house at present, though the plan is gradually being worked more remuneratively. We draw the attention of our readers to Mr. Stansfeld's able summing up of the two days' proceedings, in which he expressed, in masterly terms, the spirit of the conference. As he pointed out, the water supply is a matter for the Government to take up, by a Royal Commission, before it can be fully investigated in all its bearings. The question, at least, has been grasped as a whole, and the general lines of a comprehensive scheme have been sketched, all that is necessary now being a full and scientific inquiry into the watersheds of the country. Larger areas were the result of every discussion upon sanitary matters, the administrative element should be the unit, which once determined on, it is easy to form an aggregate; but, as Mr. Stansfeld observed, this cannot be divided, except at the expense of efficiency.

THE PICTURES AT THE ROYAL ACADEMY.

[THIRD NOTICE.]

ALMA TADEMA has sent four pictures, No. 165 is entitled "A Hearty Welcome"; nothing more exquisite has been done by this very distinguished artist. We are introduced in it to the more affectionate and domestic phase of old-world life. A matron is welcoming a young girl, probably her little daughter, on her return home. This takes place in the flower-garden in the court of a handsome Roman house; poppies, artichokes, sunflowers, all in full bloom, and a very beautiful fountain of bronze and various coloured marbles forms a charming ornament to the inclosure. At the door of the house a light is burning before the household guardians of the place. There are other figures variously employed; one child playing with a shaggy little dog, adding to the life of the subject. Every smallest detail is worked out with unapproached perfection. "Down the River" (No. 238) is upon a much larger scale. A healthy well-to-do matron is bent upon a pleasure trip with her young family. As they go down the steps to the water they are plied by the stalwart boatmen offering to take the lot on most approved terms. No inconsiderable part of the composition is a splendid bridge enriched with fine bronze statues and ornaments; over it is coming a gay procession, bringing to mind the strictures of Juvenal upon the Romans' extravagance in all that concerned the road, drawn with marvellous minuteness. A rich and splendid galley is just shooting through the centre arch of the bridge. 351, "The Pomona Festival of Dancing Round the Fruit Trees in Blossom," though as well painted, is not so generally interesting as the foregoing. Mr. Ansdell exhibits four of his boldly and truthfully painted representations of rough Highland scenery with cattle, the most important being the stray lamb, where a little lamb has just been recovered from what would seem to be an almost impossible position. In No. 237, "On Guard," he has united a very highly-finished painting of a great bull terrier with a portrait of a gorgeously appressed baby, over whom the dog is watching. The "Storm in the Glen" is also a good specimen of the artist's best work. P. Graham and James Macbeth each show a mastery over wild northern scenery; 219 by the former, "Cloudland and Moor," and "The Land of Argyle," by J. Macbeth (No. 222), could not easily be better in strict observation of nature. No. 1,386 is a grand study of inaccessible cliff, the home of unnumbered sea fowl, amid the deep shade and dark green water of the deep profound that washes the perpendicular rocks. No. 1,395, "Catherine Douglas Barring the Door with Her Arm Against the Assassins of James I. of Scotland," by L. J. Pott, would be more satisfactory if more attention had been paid to the details and furniture of the room. Several things therein are of a much later date than the time represented in the picture. John Pettie's portraits are forcible and bold. We have also by him in No. 220, "The Death Warrant," one of the finest productions of his pencil with which we have yet been made acquainted. A young and delicate prince—no doubt intended for Edward VI.—seated at the council-table seems lost in pain and difficulty, unable to bring himself to sign the death warrant, probably of his near kinsman, which one of the councillors, with pen in hand, is offering him. The grouping and expression are excellent; the richness of colour and breadth of treatment suggest an influence of the old Venetian school. The old man to the left, who sits sadly regarding the young prince, is very finely imagined. The diocese of Lincoln is to be congratulated on the acquisition of so excellent a portrait of their

bishop, the Right Rev. Dr. Christopher Wordsworth (No. 1,423), by E. Long. The prelate is represented in the rich Convocation robes, with a splendid crozier to his right hand. Scarcely less worthy of notice is No. 562, the life-long friend of the Baroness Burdett-Coutts, Hannah Brown—"Whereas I was blind, now I see." To lessen the unpleasant effect of blind eyes, Mr. Long has thrown a veil of black lace partly over the face. In so interesting and beautifully-painted a portrait, we think this was hardly necessary, though it gave the painter one more opportunity of showing his power of reproducing any texture—a power already shown in all the dress. Sir F. Leighton's portrait of the Countess of Brownlow is also a masterpiece. She stands majestically, arrayed in massive white satin robes, superbly painted, holding a great bunch of splendid dark-red roses in her right hand. The massing of colour is most skilful. Another of the Academicians who usually have chiefly excelled in historical subjects, but who this year show their power in portrait-painting, is J. C. Horsley. His portraits of Mr. and Mrs. Jessop, of Engfield Grange, Sheffield, will add to his reputation. One fancies that they must be speaking likenesses. They are solidly and cleverly painted. We hardly know which to admire most of B. Riviere's pictures. The most ambitious doubtless is that to which he has ascribed the legend, "In Manus Tuas Domine," No. 487. This is of larger size and higher aim than what he has usually produced. We have in it still the intimate knowledge of the structure and habits of animals which is always conspicuous in his works; but we have also figure-painting of a high order—something more than the domestic subjects which we have been used to. A warrior, steadfast in faith, and holding up the cross hilt of his sword, in token of the trust he feels in the great Being into whose hands he commits himself, is just about to enter the Valley of Death—symbolised by the weird bats flitting across his path, and the wriggling serpent among the crimson toadstools—the terror of the horse and hunting-dogs which have been his companions is graphically expressed; the painting of the silver armour is very fine. Few will pass over the "Winter's Tale," No. 963. Two fine colley dogs have just found a poor little girl, lost in the snow; they are none too soon, for the sleep that has come over her would soon be eternal. The foremost dog hastens to lick his young friend and warm her back to life; while his companion stands on the top of a knoll waiting to show his master that the search has been successful, if not too late. The "Poacher's Widow" is perhaps a more remarkable scene of animal life than we have had before. Whether any preserves are ever so rich as that depicted here may be questioned. If there are any such, the poachers must have a thriving time of it, if they keep clear of the keepers. The husband of the poor creature, crouching in her agony in the pale moonlight, under the flowery gorse, spilt his blood in that fair, cheerful spot, and she is well-nigh mad in her indignation. The hares, rabbits, and pheasants literally revel in the fat barley field. Close to this picture there is a very clever portrait, by Frank Holl, of Samuel Cousins, the eminent engraver, which will be very welcome to the many admirers of his great skill. Very appropriately, his engraving of the "Strawberry Girl," after Sir Joshua Reynolds, appears on the wall to the right hand of the engraver. Above this picture is a family group (No. 194), "The Wife and Children of Lieut.-Col. George Arbuthnot," by C. E. Hicks, which reminds one of Sir Joshua's style more than any portrait in the exhibition. "Signor Piatti" (No. 579), by the same artist, is worthy of the highest praise. G. Richmond's best portrait is that of Sir W. H. Stephenson (No. 56). All of those

by G. F. Watts are characterised by the same great merits and a certain mannerism which has distinguished his work for several years. No touch is unconsidered or without its effect; still there is a muddiness of colour which is seldom, if ever, seen in nature. There are several admirable portraits by Mr. W. Onless, some interesting for the subjects; all, more or less, for the goodness of their treatment. All lovers of art will be glad to see so speaking a likeness as No. 64 is of John Malcolm of Portlough. John Bright, too (No. 183), will be a welcome acquisition to the Manchester Reform Club. G. A. Storey's portrait of a lady, the centre of a flowery bower of lilies, oleander, and the pink, is delightful. She sits among the flowers there and almost looks like one of them—she is so fresh and fair—under her fanciful Japanese sunshade. Of his other portraits No. 421 is by far the best. Mr. Sandys' portrait of Mr. Temple Soanes is a bold piece of colouring, the massive blues and whites of the dress being set off by a quantity of roses and other flowers, finished with much labour and skill. One of the most delightful single figures in the rooms is Mr. Boughton's "Prisella" (No. 430), a subject taken from Longfellow's "Miles Standish." She is walking, in her calm beauty, look in hand, through the snow. It is a subject eminently fitted to bring out the excellences of this artist's manner. His chief picture is No. 330, "A Resting Place."

"Tis a sad eye that sees not
A golden apple somewhere."

Footsore, tired, and wretched, a family, who have tramped the dusty road many a weary mile, have rested awhile under a spreading oak. The older women are too miserable and borne down to have any thought but for their troubles. Not so, however, the children, one of whom is enjoying a fine rosy apple which she has somehow become possessed of. The father, too, of the family, consoles himself by patting a little bull pup, while its mother looks on approvingly. Valentine C. Prinsep's study of H. H. Sujan Sing, Maharana of Oodepoore, is a vigorous sketch. His "Room-i-Sultana" is one of the best pictures of the year. He has set himself to compose a picture with the whole of the colouring in some shade of red. The scene is a room in a palace at Futehpore—Sikri, built of dark-red sandstone; and within its curiously-carved walls, covered with delicate patterns in low relief, the fair European wife of the Emperor Akbar reclines in luxurious ease, and splendidly attired, on rich carpets; all round her are spread jewels befitting the bride of so great a prince. As a set-off against the fair beauty of the princess, a fine, dark Eastern slave fans her mistress with a white horsehair flapper. The curious and difficult problem has been worked out with perfect success.

All the pictures bought by the President and Council of the Royal Academy under the terms of the Chantrey bequest, have points of interest. The present choice seems to fall upon those who have bestowed the greatest amount of work upon actual copying of nature. Whether this may not lead to the adoption of a super-realistic treatment in those who aspire to the honour of being selected is a question well worth consideration. Take No. 21, "The Waning of the Year," by Ernest Paxton, for instance. As a fact, does the unaided eye ever see natural details so minutely as they are put down on this canvas? "Nausicaa and her Maidens" is again a favourite subject. Mr. Poynter (No. 307) has chosen the place "where the queen, now for the upstroke, quite wide off the other maids, struck the ball and made it fall amid the whirlpools" (Odyssey). As she, standing with her back to the spectator, strikes the ball away, the central group of women stand expecting the stroke; to the

left are others, washing the clothes in the river. A boy, nude, running in front adds life to the piece. The drawing in parts is unequally carried out. No. 403, "The Return of the Victors," by Sir John Gilbert, is an ideal picture rather than a representation of anything that could really have taken place. It is a fine study of colour and grouping, such as few artists of our day would attempt. On the other hand, we feel that poor Evangeline (No. 1,422) would have actually sat as Frank Dicksee has placed her, beautiful, pure, and single-hearted, trying to inspire hope and minister comfort to her aged friend, though feeling little herself. The story is graphically told. There are the two cruel ships-of-war that will pitilessly and indiscriminately carry away from their dear homes and heart-loved friends many who will never again meet in life; furniture heaped up in confusion, among sorrowing mothers with sick children; and the trained soldiers, careless of anything but the stern duty they were told off to perform. The downcast head of the old man shows how "vainly Evangeline strove with words and caresses to cheer him." The lurid light on the water well sets off the ghastliness of the scene.

Mr. Brett's landscape this year is quite as remarkable, though less pleasing, than his beautiful "Cornish Lions." No living artist surpasses him in fine eyesight and power to transfer to canvas or paper what he sees. The subject of this picture (No. 693) is called "The Stronghold of the Season and the Camp of the Kittywake." The old fortified seaboard, backed by green hills, flooded with the dazzling glow, with the ship-studded sea in front, form a picture such as few painters have had the courage or ability to attack.

CONFERENCE ON NATIONAL WATER-SUPPLY, SEWAGE, AND HEALTH.

THE fourth annual conference on these subjects held by the Society of Arts took place on Thursday and Friday in last week. On the former day Lord Alfred Churchill presided, in the absence of Mr. Stansfeld, through indisposition, and stated that the Council of the Society of Arts had offered one gold and three silver medals for the best suggestions founded upon evidence already published for dividing England and Wales into districts, for the supply of pure water for towns and villages in each district. The committee were of opinion that none of the essays sent in was worthy of a gold medal, but they had selected two which they thought worthy of silver medals, the names of the successful competitors being Mr. Frederick Toplis and Mr. Joseph Lucas. Mr. Toplis proposed that the country should be mapped out into watershed districts, and that a body of commissioners should be appointed to each district; that these commissioners should be assisted by competent legal and engineering advisers, who should have charge of the rivers and watersheds in their districts, and should have power to acquire all existing waterworks and, if necessary, canals. It might be desirable that a Minister of Health should be appointed, with a proper staff, and that he should have control, not only over the commissioners, but over all sanitary authorities. Mr. Lucas, with reference to his scheme, propounded that England should be divided into three principal districts—the Northern, the Southern, and the Midland, the divisions being made on the principle that the rivers flow east and west, and the mountains and geological lines run north and south. Considerable discussion followed the explanations of these schemes given by the authors, in the course of which it was generally admitted that England should be divided into districts for the purpose of regulating the water supply, and several speakers considered it desirable that a Minister of Health should form a member of the Government. Papers were read by Mr. A. H. Brown on "The Incidence of Rating for Sanitary Purposes in Rural Districts," by Mr. Lucas on "Subterranean Water Ridges," and by Mr. James Dillon on "The Effects of Under and Arterial Drainage on River Floods." In the course of the discussion which

followed, Mr. Rawlinson, of the Local Government Board, remarked that the waterless areas were much in excess of the water-bearing areas. They had only to go deep enough and they would get water. There were mines in the northern counties which went down from 1,800 to 2,400 feet. At the close of the proceedings the following resolution was unanimously passed, on the motion of Lord A. Churchill and Captain Douglas Galton:—"That this Conference wishes to express its entire satisfaction with the action taken by the Prince of Wales in applying to the Government for a Royal Commission to inquire into the subject of the national water supply, and earnestly hopes that the Government will take steps without any delay to carry into effect the resolution of last year's Conference."

FRIDAY.

The Right Hon. James Stansfeld, M.P., occupied the chair throughout the day.

DR. THORNE THORNE gave a lucid description of his investigations into the recent disastrous outbreak of enteric fever at Caterham, Redhill, Earlswood, and Bletchingley, which he distinctly traced to the employment in an adit, between the Caterham Water Company's wells, of a man who was suffering from a mild form of enteric fever, and who was compelled to evacuate whilst in the adit. Other cases of enteric fever epidemics conveyed by water supplies at Guildford, Over Darwen, and Lewes, were described. From these he drew the following conclusions:—1. That the view, to the effect that even a comparatively minute quantity of the poison contained in the evacuations of enteric fever patients, may, when subjected to conditions favourable to the development of that poison, lead to the specific infection of very large volumes of water to which it has gained access, is fully borne out. 2. That a special danger attaches to the prevalence of the mild—or, as they had been termed, "perambulatory"—cases of enteric fever, by reason of the intensely poisonous nature of the diarrhoea which characterises that disease. And having regard to these facts—3. That all possible sources of excremental contamination in the vicinity of watercourses should be rigidly dealt with. 4. That care should be taken, in connection with works for the construction or storage of water, to exclude from employment all persons suffering from any diarrhoeal affection.

In reply to various questions, Dr. Thorne said he attributed the comparatively light mortality in proportion to the number of cases to the extreme dilution of the poison; that in every case where the poison was presumably much diluted the epidemic was comparatively mild. He had not allowed the Caterham water to be analysed, as he did not believe the poison germs could be chemically distinguished. Mr. Cresswell quoted the Cokermouth case, in which the dictum was laid down by the Master of the Rolls that it is not necessary to prove the existence of a nuisance polluting a source of water supply in order to obtain an injunction against the polluting party; it is sufficient, for legal purposes, to show that there is a potentiality of water-pollution.

MR. ERNEST HART followed, with a paper upon the epidemics of enteric fever produced by polluted water supply since the passing of the Sanitary Act, 1866. Every considerable epidemic caused by bad water during the past 13 years had been investigated by the Government, and of these, amounting to some hundreds, all but a few have been proved to owe their origin and spread to polluted water alone. In the subsequent discussion Mr. Baldwin Latham, C.E., gave numerous cases of enteric fever outbreaks and immunities from them in Croydon and neighbourhood, to show that the disease spreads directly the water rises in the subsoil of a source of supply, and that the exposure of contaminated water to the air and light removes the poisonous qualities of the supply.

DR. ALCOCK, Sunderland, urged that, on account of the difficulty of ascertaining facts of possible pollution from private water companies, the supply of water should be transferred from companies to local authorities. Dr. Thorne explained that the Caterham water company afforded him every possible facility and information, even while sceptical of his theory, and had since adopted his suggestions for disinfecting the adit and wells. After further discussion the following resolution was proposed by Mr. Ernest Hart:—"That, since a comparatively minute

quantity of the poison contained in the evacuations of the patients of enteric fever may, it is believed, when subjected to conditions favourable to development of that poison, lead to specific infection of our large volumes of water to which it has gained access, all sources of excremental contamination in the vicinity of watercourses should be rigidly dealt with during their construction or repair, and in their use." Mr. Hart went fully into the occult question of the presumed growth, propagation, and destruction by oxidation, of enteric fever germs, and urged the importance of exercising the greatest vigilance over water sources. Mr. C. N. Cresswell seconded the resolution, on the ground that he believed its passing would aid in preventing the intermarriage of the domestic well with the domestic cesspool, and because such an expression of opinion from the Conference would strengthen the hands of local authorities in carrying existing legislative powers into practice, and in inciting them to demand from the Government further reforms in the prevention of river-pollution. The President having pointed out the practical character of the resolution, it was carried unanimously.

In the afternoon methods of sewage were dealt with. The subject was opened by a paper read by Sir HENRY COLE, on "The Progress with Sewage since the First Conference in 1876." He held that while the public ignorance on sewage subjects was still universal and deep, it was becoming less so. For all that, every house in London was but a ventilating shaft for sewer gas, and the same evil prevailed in many large towns; the Thames in the metropolis remained as foul as ever, and in large provincial towns passiveness only appeared to reign. Two or three conclusions respecting farming by sewage now seemed to be admitted. (1) That the storm water must be kept out of the sewers; (2) that precipitation must take place before the sewage flows on the land; (3) that filtration of some kind after precipitation was most desirable; (4) another conclusion was, that towns cannot make a profit out of water-carried sewage. He thought compulsory federation of small places under a united local management was ripe for the Local Government Board at once to insist on, and on this point read some correspondence which had passed between the Duke of Sutherland and the Local Government Board. Sir Henry Cole added that he had thought the progress of sanitary science had been retarded by the prejudices of the inspectors of the Local Government Board in favour of irrigation; but in reply to a complaint he had forwarded to that authority he had received a reply from the present President of the Board, stating that the inspectors are instructed not to express publicly any opinion upon the proposals into which they are inquiring, and that the Board are "only too glad to have brought under their notice any scheme which can be reasonably relied upon as combining economy with efficiency in sewage disposal." In conclusion, Sir Henry pointed out that in the present state of public opinion and knowledge, strong compulsory legislation on sanitary matters is hardly possible and not desirable.

Mr. CRESSWELL followed with a paper in which he described in humorous and sarcastic terms the successive attempts which have been made during the last 30 years by Richmond and other towns in the Lower Thames Valley to get rid of their sewage. Hemmed in by Royal parks on either side, a river in front, and a railway behind, Richmond had yet been urged by the Thames Conservators and the Local Government Board to discontinue passing its sewage into the river, while every scheme for conveying it away had been successively frustrated. The latest scheme was that prepared for the "United Drainage Board" of the whole Valley by Colonel Haywood and Mr. Peregrine Birch, and involved the pumping of the sewage over 800 acres of land near Moulsey, and this had been strangled by the House of Commons in its second reading.

Mr. RAWLINSON, chief inspector of the Local Government Board, denied that instructions were given to the inspectors to recommend irrigation schemes. For many towns the requisite land for a sewage farm could not be obtained, and in the manufacturing districts it was of paramount importance that the water should be clarified on the spot and utilised for trade purposes. As to the alleged dangers from the pollution of rivers, there were two sides to the question, and he was

not convinced that any injury to health could be proved from this cause except where the water was used for potable or domestic purposes. Captain Douglas Galton thought the duty should entirely rest on the Metropolitan Board of Works to carry out their original idea of removing sewage and purifying the Thames. After further discussion, Mr. Cresswell agreed to the following amendment of the resolution with which he had concluded his remarks:—"That this conference recommends the Council to arrange that a deputation wait on the Government to urge the necessity of taking further legislative measures to prevent the continuance of the pollution of the Thames by sewage." This was seconded by Sir Henry Cole, and carried by a large majority.

Mr. BALDWIN LATHAM, C.E., described the system of sewerage and sewage disposal he has carried out for the Croydon Rural Sanitary Authority for Beddington, Merton, Merton-Rush, Mitcham, Morden, and Wallington, an area of about 16 square miles, with a population of 16,000. A scheme is now being rapidly carried out, by which six-sevenths of the sewage of the combined districts will be conveyed by direct gravitation to an area of 38 acres of land located partly in Wimbledon and partly in Mitcham. The sewage will be pumped to a height of 25ft., and dealt with by filtration through the soil. The total cost of the undertaking is estimated at £90,000, and will probably be exceeded on account of the rapid increase of population. In reply to questions, Mr. Baldwin Latham expressed the opinion that a filter bed 6ft. thick and an acre in extent will purify the sewage of 3,000 persons.

Lieut.-Col. A. S. JONES, V.C., gave an account of the seventh year of his dealings with the town sewage of Wrexham, on his sewage farm at Hafod-y-Wern. His experience had shown that a sewage-farm, given the right sort of land and undiluted sewage, would pay the farmer a rent of £1 to £5 per imperial acre, and make a fair profit for his time and capital. He also described the pneumatic ejector which had been invented by Mr. Isaac Shone, and which was regularly used on his sewage farm, for the intermittent lifting of crude sewage, at the rate of about 4,000 gallons per hour to a height of nearly 40ft. An advantage was that one air-compressing engine would work a large number of ejectors at any distance from the engine. In reply to Mr. Cresswell, Col. Jones expressed his opinion that such a pneumatic system would be very useful in towns on the flat, such as Brentford and Southport. He advocated the entire exclusion of storm water from sewers, and believed that means of flushing would be easily found by temporarily damming up the sewage, or utilising the water mains.

Mr. HENRY MASTERS explained, by means of diagrams, his double-check system of house drainage, for which he claimed great simplicity. In its most simple form the system consisted of a pipe drain from the back to the front of the house, joined at the back of the house to the vertical soil-pipe, to which were connected the w.c. pans. To cut off the house from the public sewer, there were put down two common siphon traps, connected together by a short junction pipe, to which was attached a large iron escape pipe, extending above the house roof. He also provided for sudden flushing of the pan and soil-pipe by making the pipe from the flush tank of large dimensions, with valve and way to pan of equal capacity. A point in applying his system was that every speciality or mechanical contrivance was avoided; he used the common form of trap, ordinary glazed ware pipes, sometimes with Stanford's joints, and stout cast-iron soil and air pipes.

Mr. E. G. BANNER explained his system of house sanitation, and performed some experiments with a view to exhibit the exhaust power of the cowl he introduced in 1874. A glass tube after being filled with the smoke of a taper was speedily cleared by blowing upon the cowl at the top; and a 60ft. length of flexible pipe was similarly freed from smoke with the aid of a pair of bellows. Mr. T. Welstencroft and others in the audience pressed Mr. Banner to repeat the experiment on the tube without the cowl; this being done, the smoke passed off when Mr. Banner blew over the top of the tube, and indeed when a cork was removed from the side of the tube an updraught was created, and the fumes escaped without further assistance.

Dr. VACHER explained the pail system as carried out in several towns in Lancashire, in an

address which gave rise to some discussion as to the cost and convenience of the method as practised in Rochdale, Warrington, and parts of Manchester.

The CHAIRMAN closed the conference by an address, in which he summarised the results of the two days' proceedings. He congratulated the meeting upon the mode in which the work had been carried out, and observed that the varied subjects for thought and the suggestive papers would be inducements to lead to a continuance of these conferences. He wished there had been more time to discuss the pail system. The conference had in previous years expressed the opinion that this was a vast improvement on the older methods of disposal, those of privies and middens. The town of Rochdale was adopting a new method of collection, and particulars as to the comparative cost of this and other systems would be looked forward to at the next conference. Whatever the defects of the pail system, it dealt with the question of disposal at its very source, avoided the possibility of the generation of sewer gases, and, however troublesome and expensive its working might be, in adopting it a town was not sinking money on large works which might turn out to be constructed on a wrong principle, or even inflicting a greater injury on some other district. Where there was not a dense population, and no convenient outfall, the pail system was probably the least costly method of sewage removal. With reference to the question of water supply, discussed on the previous day, the conference had, he thought, acted wisely in throwing upon the Government of the day the *onus* of inquiry into the subject by Royal Commission. Should the Government accede to this wish they might anticipate that the question of supply would be investigated in the fullest manner and on the broadest lines; should the Government decline to do so, he thought the Society of Arts ought to be prepared to act in the matter. An extremely important subject was that of the connection between the contamination of water supply and the spread of enteric fever, and they would have no reason to repent the resolution they came to, based as it was on clear and confirmed scientific evidence. Sir H. Cole had urged that an inquiry office should be started by the Local Government Board, and he believed the chief obstacle in the way of this suggestion being carried out was that of ways and means. He had also advocated the federation of rural local authorities, and this, indeed, had been the tendency of the whole proceedings, that both for water supply and sanitary purposes large areas of local government should be adopted. He thoroughly concurred in this, and believed that these larger areas ought to be a portion of the long-talked-of county board scheme. In expressing a hope that they would meet again next year, he ventured to think that the conference proceedings had been neither ineffective, unimproving, nor unimportant, and that members would take home with them many useful ideas for future consideration.

The proceedings closed with a vote of thanks to Mr. Stansfeld for his conduct in the chair and his closing address, proposed by Dr. Yeld, of Birmingham.

NATIONAL WATER SUPPLY EXHIBITION.

A HIGHLY instructive exhibition of plans, sections, apparatus, and appliances, illustrating various means in the adoption and maintenance of a National Water Supply, is now open in the gallery of the Royal Aquarium at Westminster, to which we may draw attention. The arrangement into sections and the details of the different exhibits have been carried out by Mr. John T. Carrington in a manner that reflects credit upon that gentleman. We may briefly say at the outset that the idea of a collection of this kind originated from Mr. Mitchell, who compiled the "Notes on Previous Enquiries" for the Society of Arts. There is doubtless more to be learnt of scientific facts and data by a collection of models and diagrams than by any other means, and the management of the Aquarium have wisely taken advantage of the idea. Having paid a visit to the exhibition, we find the gallery is divided into several sections. In section I. the collection and storage of rainfall is illustrated, Mr. Symons exhibiting several diagrams. In section II. Mr. J. Lneas, one of the prize essayists of the Society of Arts,

shows a large map, in which the hydrogeological survey is applied to the geological map, indicating the difference in the two works. The maps showing water contours on the chalk system and the several sections between the Darent and the Mole, drawn to a large scale, will be found specially interesting to those engaged in these pursuits. Speaking of maps, we may mention Mr. Stanford's admirable Library Ordnance Map of London, showing the geological boundaries. Mr. Jordan's model of the great Wealden area, and Mr. de Ranee's diagrams exhibiting the absorption of various rocks, besides others, illustrate thoroughly the geology of the country round London. Many of the plans for bringing water to the metropolis from the Welsh and Westmoreland lakes are to be seen. Several portable spongy iron filters are exhibited by Messrs. Defries and Sons and Messrs. Griffin and Co.; and Dr. Clark's and Prof. Wanklyn's apparatus for hardness and testing. A very interesting section is No. V., devoted to several appliances. Among these we notice the Diamond Rock Boring Company's apparatus, and Messrs. Blakeborough's water fittings, the latter exceedingly well turned out; also Messrs. Warner and Son's pumps, &c. In the water pollution department is a bottle of sample water from the Pontypool Waterworks, showing live leeches, exhibited by Mr. Williams, of Pontypool. In another department we observe a fine series of views of old London, from the collection of J. E. Gardner, many illustrating old wells, conduits, and watercourses, such as the old conduit, Cheapside, Hampstead Wells, sketches of the Fleet, &c. Views, including some exceedingly choice engravings and sketches of old London Bridge, Walbrook, Lambeth, Bridewell, Clerkenwell, Islington, Cannonbury, Highgate, Newington Green, will well repay the archaeologist and student. We note among these a fine engraving of the Fleet marked by G. Dance; an arcade with centre enpola, in the Italian style; a fine mezzotint view of Hanover-square, engraved by Pollard and Jakes; the Old Queen's Head, Islington; a three-story overhanging house in a 16th century style; the old Angel Inn, Islington; a red brick and tile building of Queen Anne character. Though an experiment, we hope the collection will secure the patronage it deserves and induce periodical exhibitions of a like character.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE tenth ordinary meeting of the session was held on Monday evening, the newly-elected President, Mr. John Whichcord, in the chair. Messrs. Thos. Henry Wheeler, Heathfield, Wandsworth-common; and John Groom, 21, Finsbury-circus, E.C., were elected as associates; and Mr. John Robert Bourne, Bedford Office, Bloomsbury, W.C., was elected as an honorary associate.

THE FORTHCOMING AUSTRALIAN EXHIBITIONS.

The PRESIDENT said that the Council had experienced considerable difficulty in arranging for the proposed Australian exhibitions at Sydney and Melbourne, owing to the short time at disposal in which to make preparations. No doubt this inconvenience would be equally felt by intending exhibitors, and he would therefore call attention to the intimation they received from the Prince of Wales, that the Royal Commissioners would be willing to receive any drawings which were exhibited in Paris last year. No delicacy need be felt by architects in availing themselves of this invitation, as scarcely any of those who would visit the Australian exhibitions were present at the Parisian one. The selection of drawings would be intrusted by the Royal Commissioners to the Council, who would act as a committee, and Mr. T. Roger Smith, who assisted at the Paris Exhibition, had again volunteered his services as honorary secretary. Unexecuted or competition drawings would not necessarily be rejected. He would earnestly appeal to members to do their utmost to aid in making such an exhibition as would do credit to English architecture, and show to our brethren in Australia the character of the works now in progress in the old country. Mr. WHITE (secretary) read the circular-letter which it was proposed to send out to every member of the Institute, which stated that drawings were to be sent in to the gallery at South Kensington Museum on or before the 4th June. Mr. C. BARRY reminded members that the

Institute had again been intrusted, by the Royal Commissioners, as in the case of the Paris Exhibition, with the management of the architectural sections of the exhibitions. Such a delegation of authority by the Royal Commissioners, who had set aside their own machinery for the purpose, was as creditable as it was gratifying to the members; and since the responsibility was great, he trusted the profession would fully avail themselves of the invitation to exhibit, and make the exhibitions successful as far as they were concerned.

Mr. HAYWARD asked what arrangements were made for the return of the drawings sent to Australia. Satisfactory arrangements seemed to be made for the Sydney exhibition, but he should like information as to the provisions for the safety of the drawings when sent from Sydney to Melbourne next year, and their return. The PRESIDENT explained that the Royal Commissioners undertook not only to forward but to return all drawings intrusted to them, and also to insure them against injury or loss. Mr. HAYWARD further inquired whether drawings sent for the first exhibition would also be necessarily sent on to Melbourne, for some exhibitors might not be willing to spare their drawings for so long a period. The PRESIDENT replied that if any such condition were made by an intending exhibitor it would be considered by the Royal Commissioners, who could of course accept or reject their drawings in consequence.

The SECRETARY mentioned that an exhibition of sanitary appliances is to be held at Cork in connection with the meeting of the British Medical Association from the 5th to the 8th August next. He also read a letter from Mr. W. W. Pocock, stating that the remaining portion of a building belonging to the Carpenters' Company, in London-wall was about to be removed. It contained some Tudor work, and a ceiling probably painted by Wren and his assistants; the hall would be open to the inspection of members until it was pulled down. The PRESIDENT remarked that Professor Donaldson had given the Institute an autograph of Wren's, to be added to his design for St. Paul's hung on the stairs. Mr. JOSEPH CLARKE said some effort ought to be made by the Carpenters' Company to preserve this Tudor and Jacobean work, either by building it into the new hall or by keeping it therein. There was not room to receive it at the Architectural Museum, or it might have been exhibited there. On the suggestion of Mr. Barry it was agreed that a letter be written in the name of the council asking for measured drawings of the old work, to be added to the Institute collection.

PROPOSED PORTRAIT OF THE EX-PRESIDENT.

Mr. JOSEPH CLARKE referred in eulogistic terms to the mode in which Mr. Charles Barry had discharged the duties of President, stating that looking back as he could to the days of Earl de Grey, he had never known the chair so well filled. He suggested that Mr. Barry be asked to allow his portrait to be painted, and that the members enter into a subscription for the same, in order to present it to the Institute as the first of a series of such portraits. Mr. CLARKE concluded amidst applause, by moving a formal resolution to this effect. Mr. C. F. HAYWARD seconded the resolution, and suggested that the portrait should correspond in size to those of Sir M. D. Wyatt, Mr. T. H. Wyatt, and Sir G. G. Scott. Mr. O. HANSARD wished the resolution so to be altered as to state that the portrait was one of a series; but Mr. WATERHOUSE, A.R.A., deprecated this, remarking that for an ex-president to have his portrait presented to the Institute ought to be regarded as a very great compliment to him; it might happen at some future day that they would not care to have the portrait of an ex-president. Mr. CHATFIELD CLARKE expressed a hope that a thoroughly good portrait would be secured, which would be at once a credit to Mr. Barry and to the Institute. The resolution was carried unanimously, and Messrs. Joseph Clarke, C. Foster Hayward, and Horace Jones, were appointed hon. secretaries of the subscription fund.

BILLS OF QUANTITIES: THEIR PROPER RELATION TO CONTRACTS.

Mr. JOHN HONEYMAN, of Glasgow, read a paper on this subject, the first portion of which will be found on our next page.

At its conclusion a discussion took place, opened by Mr. WYATT PARWORTH, who inquired

as to the character of the education of a valuing surveyor in Glasgow.

Mr. ARTHUR CATES expressed his thanks to Mr. Honeyman for the able manner in which he had introduced the subject, and for the strong originality with which he had treated it. He thought, however, the lecturer had not sufficiently weighed the importance of his remarks in reference to the measuring surveyor and his honesty of purpose. It was true that his remarks had been subsequently toned down and explained, but he (Mr. Cates) thought that they should be somewhat modified before they appeared in the Transactions. It had been suggested in the paper that the measuring surveyor might increase the quantities to a considerable extent, thus benefitting the contractors at the expense of the proprietor for the sole purpose of increasing his percentage. "The surveyor and the contractor alone," Mr. Honeyman had said, "were benefitted by the quantities being excessive; every penny unnecessarily added to the contract price was a direct gain to both." That the inducement of getting 30s. for every £100 added to the cost would be powerful enough to lead the surveyor to increase his quantities it was certain was incorrect, and he hoped Mr. Honeyman would modify the assertion. The author had seemed to infer that the taking out quantities was, under the old system, done without cost to the proprietor. This was a very great delusion, as the contractors always put down in their tenders the cost they had incurred in estimating the quantities. The change was made in order that this cost should only be incurred once by all those who tendered, and so that each should obtain accurate quantities. Again, the London system had hardly been accurately described, for it had been inferred that the proprietor had no equivalent for his quantities. Certainly he had a most complete and thorough equivalent, for assuming, as one must do, that the quantities were properly prepared, all the contractors were placed on an equal level and a correct basis on which to make a tender. The experience of Mr. Honeyman seemed to have been very different to that he had himself met with. If a surveyor were a competent man, he could not see in what manner extravagant cost would be involved in his taking out the quantities. An illustration had been adduced where the same contractor obtained the contract for adjacent buildings by the same architect and afterwards claimed to be paid by both proprietors for the party wall, on the ground that it had been shown in both sets of quantities. In this case the architect and surveyors must have been very negligent to allow the contractor to be able to claim for work which he had never done. At the first General Conference of Architects in 1871, this question of quantities was introduced by Mr. T. H. Wyatt, and a special committee was appointed to consider and report upon it. They drew up a list of questions as to the taking out of quantities and the employment of surveyors, which were forwarded to members of the Institute. Some sixty replies were received to these inquiries, and the committee made a report at the Conference in June, 1872, in which they stated that, for the present, they were satisfied that it would not be practicable to lay down any fixed rule for the guidance of the architect in dealing with "quantities." The committee added that "it would appear reasonable" that the bills of quantities which express in an exact form the intentions of the architect as set forth in his general drawings and specifications, ought to form a part of the contract, and be dealt with as a recognised exposition of the responsibilities of both employer and builder. The system adopted by many eminent architects, of nominating a surveyor who should prepare quantities on his own responsibility, which quantities became a part of the contract, might, in cases where time pressed, be advantageously adopted, provided that the builder be relieved from responsibility as regarded the quantities. Where the architect supplied the quantities for carrying out his own designs, it should be with the knowledge and concurrence of the employer, and the quantities should form a part of the contract. This report was received by the Institute. In 1874 the subject was again referred to this committee, who reported back that they found no reason for modifying their conclusions, but they could not submit any more definite proposal to the members. He thought Mr. Honeyman's scheme for measuring and remeasuring when the building was erected would involve increased

chances of error, and great delay in the final settlement of accounts, and while agreeing in the recommendations of the special committee, he saw no grounds for any change in the London system.

Mr. C. BARRY said Mr. Honeyman had gone on totally false premises, as far as the London system of contracting was concerned, in supposing that a single surveyor was appointed, and that by the architect. The custom invariably adopted was for two surveyors to be appointed—one by the architect to take out the quantities, and the other by the builders to see that he is justified in his estimates. Cases had occurred where there was that trust felt in the choice made that one man acted for both parties, but it was by mutual consent; the architect had the power to choose, and the builder to refuse his services. He could not imagine any more fair system than this could be devised, and it was one which had the enormous advantage of affording an opportunity to the client to ascertain as far as possible the cost from the outset. Mr. Honeyman appeared in his paper to have set up giants of his own imagining for the purpose of knocking them down. He had, indeed, charged surveyors with being the servants of the contractors and so having an interest in taking out the measurements very fully. Such a statement as this ought hardly to be made and published under the authority of the Institute. It was not true of surveyors as a body, who would not do anything wrong wilfully, although being human they were liable to make mistakes. He agreed with Mr. Cates that mistakes would be more likely to occur if the measurements were made on the buildings than on the drawings in the quiet of an office. Mr. Honeyman had also said that formerly the experience of those tendering came into play as a safeguard against excessive cost, but that now that the amount of tenders turned on the mere variety of rates, architects must either guarantee the accuracy of the quantities or arrange for securing the interests of the proprietor in spite of errors in those. He forgot that an honest difference in the amounts of tenders on the same quantities depended not alone on the relative rates of profit, but on the amount of capital invested in the business, the occupation of the builder's staff, his stores of material, or some foreseen change in market prices. Again, if the quantities were systematically too high, the contractor would not be able to depend on them in tendering. The pecuniary responsibility of surveyors had been treated in the paper in a scornful manner, but this was not such a shabby guarantee as had been suggested. He had known cases where surveyors who had made serious omissions had paid the contractor's charges without demur, although in some cases the proprietors had not recouped them this payment for work of which they received the sole benefit. In parts of the paper he cordially concurred, although he considered his case as a whole had completely failed, and he would conclude by moving a vote of thanks to Mr. Honeyman.

Mr. ALFRED WATERHOUSE, A.R.A., remarked that, in describing the Glasgow system, Mr. Honeyman had not told them what it cost—a most important point. Although the paper would be useful in leading members to think more seriously of the quantities question, he did not think the author had hit the nail on the head. The system practised here was very anomalous, in employing a surveyor to prepare quantities for the contractors, and yet not taking the results of his labour as a basis of contract; and if architects could persuade clients to allow this to be the case many of their difficulties would be at an end.

Mr. RICKMAN differed from Mr. Barry in the opinion that the system most largely adopted in London was that of employing two surveyors. It was becoming more largely into vogue to engage but one surveyor (Mr. BARRY explained that he referred to the employment of one surveyor by mutual consent), but in very large buildings there were obvious advantages in engaging two professional men. The surveyor should, he thought, be kept as far as possible free from pecuniary responsibility. Under the old system which prevailed in London a generation ago, every item was measured up, and the whole was most difficult of variation. In the present mode of measuring up it was easy to allow for alterations as the design progressed towards execution. He thought measuring surveyors of London would hardly care to become licentiates of the Institute, as suggested

by Mr. Honeyman: they would, he trusted, take a much higher position than that.

Mr. CHATFIELD CLARKE observed that Mr. Honeyman had not given any data as to the cost of his proposed system of measuring. He should himself studiously avoid making quantities part of the contract.

The PRESIDENT, in putting to the meeting the motion of thanks to Mr. Honeyman for his exhaustive paper, regretted there had not been more time for the consideration and discussion of this useful and practical subject.

Mr. HONEYMAN, in reply, acknowledged the hearty manner in which the vote of thanks had been accorded. He regretted his references to the relative positions of measuring surveyors and contractors, alluded to by Mr. Cates, should have been capable of being misunderstood; if they appeared to cast any imputations upon either he should be most anxious to modify them. What he had intended to show was that the surveyor was responsible to the contractor, and that this was a wrong position in which to place the two parties. To say that the surveyors would knowingly increase the amount of the contracts for the sake of the additional percentage was no more reasonable than it would be to accuse architects of a similar desire to increase the cost to clients. It must be remembered that he was not only referring to the better class of surveyors, who were incapable of such practices, but to the whole body of surveyors throughout the kingdom. As to contingencies, in the Edinburgh system there was always a separate item for these. As to the London system he had thought that but one surveyor was employed, and that by the architect with the consent of the contractors. Allusion had been made to the case where an Edinburgh contractor claimed to be paid twice for the same wall, but he ought to have said that in that case the contractor considered he was aggrieved by other omissions, and wished to set it off or to have the work re-measured. The cost of the Glasgow system varied according to the character of the work. A great deal of the work was measured and re-measured for from $1\frac{1}{2}$ to 2 per cent., i.e., for both operations, but the majority of it probably cost for both measurements $\frac{2}{3}$ per cent. on the total cost, and it was found that the better class of Glasgow surveyors took out the quantities with almost absolute accuracy. His main argument, however, had been that bills should be made the basis of the contract, and he still believed this could best be done by the process of measurement and re-measurement.

BILLS OF QUANTITIES: THEIR PROPER RELATION TO CONTRACTS.*

THE modes of measuring artificers' work vary considerably in different parts of the country; and, still more markedly, in other matters connected with contracting the practice is diversified. In some localities the quantities are taken out by a special class of men variously styled quantity-surveyors or measurers, in others by architects; in some they are taken out with the greatest minuteness and with elaboration of detail, while in others the descriptions are general and comprehensive, and the contractor is obliged to interpret the details for himself; in some it is customary to base the contract upon the plans and specifications alone, while in others the practice so greatly differs that the contract is based upon the bill of quantities alone, and there is no such thing as a specification referred to at all. In these circumstances it is extremely probable that defects exist in many, if not in all, the methods of contracting for buildings now generally in use, and it is perhaps equally probable that each of the various methods possesses certain merits peculiar to itself, or more or less common to the other. An earnest and unprejudiced investigation into these peculiarities, then, cannot fail to be interesting and profitable; and I am sanguine enough to hope that it may lead to the conviction that the construction of a system superior to any of those now in use is not only desirable but practicable. It is with the desire that I may be able to assist, however feebly, towards the realisation of such a consummation that I now address you.

Before proceeding to consider the various modi-

fications which have been made, or which ought to be made, in the relative positions of building owners—or proprietors, as I shall call them—architects, surveyors, and contractors, I wish to direct your attention very specially to the elementary truth, which we must never lose sight of, that in contracting the normal state of matters is this: the architect having completed his plans and specifications occupies in relation to the contractor exactly the same position as his client the proprietor, who might in point of fact get in tenders himself without the further intervention of the architect. It is generally convenient for the proprietor that the architect should get in the tenders for him, but in doing so the latter, if he has followed his employer's instructions and represented what is wanted by sufficiently explicit plans and specifications, incurs no other responsibility. He has nothing to do with the means which the builder may employ to ascertain the value of the work. One builder may measure the work himself, another may get some one to measure it for him; one may have it minutely measured, another may do it roughly, or even guess what the value should be. All the proprietor, or his agent, the architect, wishes is an offer *bona fide* for the execution of the works he has illustrated and described. That, I say, is the normal relation of the parties in estimating. In these circumstances it is a matter of indifference to a proprietor or his architect what quantities of materials a contractor uses, so long as he executes his work satisfactorily in accordance with the plans and specifications; the onus of ascertaining how to do this at the smallest cost rests upon him, and competition with others effectually keeps him from careless or wilful exaggeration. This responsibility was in former days fully accepted by contractors, and men who understood their business thoroughly had no difficulty in tendering without the intervention of a third party; moreover, they enjoyed a distinct and legitimate advantage over others who were less competent or experienced, the tendency of which was beneficial in many ways. Now, however, so great a change has occurred in this respect that it would be extremely difficult to find in any locality contractors able or willing to tender for a work of any importance without bills of quantities. The present generation of builders has become accustomed to them, and it may be safely said that many could not give an intelligent offer without them. The normal arrangement, as I have called it, is henceforth inapplicable, and it is generally admitted that it is impossible now, even if it were thought desirable, to return to it. But, and this I wish particularly to emphasise, it by no means necessarily follows that the change in the practice of contractors should affect in the slightest degree their proper relation to proprietors. The change has been introduced primarily to facilitate the work of the contractor, but the proprietor may and ought to share in its advantages. There is evidently something radically wrong if its effect is to lead the proprietor with expense and responsibility for which he has no equivalent; and it is the duty of the proprietor's architect—or, speaking for proprietors generally, I may say it is the duty of this Institute, to see that we do not drift into the use of a system which must produce such results. This duty is, I think, brought home to us forcibly by the following among other considerations:—First, and most directly, because it is the proprietor who has to pay for the surveyor's work. In some cases this payment is made wholly or in part through the contractor; but in every case it comes out of the proprietor's pocket either directly or indirectly, whether he realises the fact or not. In one shape or another it is a charge which the proprietor must bear, and it is therefore clearly the duty of the architect in the interest of his client to see that the money is judiciously expended and that a fair equivalent is obtained. A second reason why architects should now devote special attention to this subject arises out of the circumstance that in times past they have too much neglected it. They have failed to control the development of the system which as it exists is eminently unsatisfactory—especially for proprietors—although regarded by our profession with a complacency or indifference which seems to me, I confess, astonishing. A third reason for their more active interference is that they may control the further development of the system, and by their united action counteract tendencies which are mischievous, confine the measurer to his legitimate province, and fully

* A paper read by JOHN HONEYMAN, F.R.I.B.A., of Glasgow, before the Royal Institute of British Architects, May 19th, 1879.

utilise his work for the benefit of the proprietor, who pays for his services. Of course, as we shall afterwards see, such a course is not incompatible with due consideration for the interests of the contractor. He is, and the quantity-surveyor ought to be, directly under the control of the architect, who is no more likely to act unjustly to the one than to the other.

Before suggesting some changes which I think would be advantageous, it will be necessary to refer at some length to the existing systems in different parts of the country, and to examine critically the special features of each which bear upon our subject. I have therefore arranged my remarks under the three following heads:—First, the actual state of matters; second, a critical examination of the prevailing systems; third, proposed changes.

I.—The first of these need not detain us long, because the members of the Institute already know a great deal about it. You are all familiar with the modes of measuring and contracting in some localities, and many of you have had experience in all parts of the country from Land's End to John O'Groats. I must, however, for future reference state succinctly the distinctive characteristics of the systems now generally recognised. First, and by far the most extensively practised, is that to which you are accustomed here in London. In your practice the bills of quantities, or the "Schedules"—as we call them in the North, and I think the term is more convenient—after they have been issued are practically ignored by the architect. They are, whether prepared at the instance of the contractor or under the direction of the architect, regarded simply as aids to the contractor in arriving at an intelligent idea of the cost of the works, and it is the exception when they are still further utilised as guides in fixing the cost of additions and deductions. Formerly, and not many years ago, it was usual for the contractors to choose the surveyor, and in works of considerable magnitude a second surveyor was employed by the proprietor as a check upon the other. This cumbersome and expensive system is still occasionally adhered to, but it is rapidly losing favour and even now may be regarded as exceptional. As a rule now the architects, acting as the proprietors' agents, select surveyors in whom they have confidence, whose bills of quantities are generally accepted by contractors as a safe guide. But, strange to say, the architects have failed to recognise the fact that this interference on their part necessarily alters the relation of the schedule to the contract, and they still assert that it has no relation. It is therefore ignored; the proprietor is supposed to have nothing to do with it, and an attempt is made to free him from responsibility by a legal fignment—the arbitrary transference of the surveyor's services to the contractor at a certain point.

With slight modifications, which for our present purpose it is immaterial to mention, the London system is followed throughout England and Ireland; but generally the interference of the architect is carried a step further in the Provinces; he does not select a surveyor to take out the quantities, but he takes them out himself, thereby incurring serious responsibilities over and above those which his position as an architect necessarily entails; in fact, he becomes responsible both to the proprietor and the contractor, an anomalous and dangerous position. Both in the London and the English provincial practice the surveyor is paid by the contractor, unless there is an express agreement to the contrary.

The Edinburgh system resembles that of England in many respects, the principal differences being these: First, contractors never have anything to do with the selection of the surveyor or measurer, as he is called, who is always employed by the architect. Second, the measurer is paid by the proprietor. Third, the schedule is referred to in the contract. It is lodged with the architect with the various items cashed and summed up, and the rates contained in it regulate the cost of additions or omissions which may be ordered in the course of the work. It is also a useful guide to the architect in certifying for instalments. A somewhat similar arrangement is sometimes made in England and Ireland, but in these cases the priced schedule is generally lodged under seal, and even with this modification the practice is by no means common. There are some other shades of difference in provincial practice, but no other system is sufficiently distinctive to merit notice except that which

prevails in Glasgow and the West of England. In Glasgow the schedules have superseded the specification altogether, and it may almost be said that a specification is never referred to in the contract at all. The architect selects the measurer, who, with the aid of the drawings and specification, or such substitute for that as he may get, prepares a detailed schedule of quantities. Copies of this are issued by the architect to selected tradesmen, who are invited to tender by a certain day. These schedules are returned to the architect with rates filled in at each quantity, the amount extended, and the total summed up at the end. A letter accompanies, or more generally is attached to, the schedule, in which the builder offers to execute the work in accordance with the drawings, and "to the extent of the schedule" for the sum brought out by the addition of the extended prices, it being further provided that the whole of the work shall be measured after it is finished, and whether it turns out to be more or less than estimated the cost shall be determined by the rates contained in the schedule; or, where these do not exactly apply, by others strictly in proportion to them. Having considered the various offers, the architect writes on behalf of the proprietor accepting the one which is preferred, and that completes the transaction; in nine cases out of ten there is no more formal contract. When the work is in progress, and when it is finished, the measurer measures it, and prepares a final measurement applying the schedule rates to the various items, and so bringing out the total sum to which the contractor is entitled. This document is examined by the architect, and if he is satisfied that it is compiled in accordance with the estimate he signs it as a final certificate. Half of the cost of the original schedule and subsequent measurement is deducted from the contractor's accounts, and the proprietor pays the full amount—that is ostensibly the half, but in reality the whole. In the East and North of Scotland the Edinburgh system is more or less closely followed, while in the West the Glasgow system prevails; the principal difference in the smaller towns being that in most cases the architects prepare the schedules themselves instead of employing measurers.

From the foregoing brief account of the existing state of matters, it will be observed that, leaving out of account the now comparatively rare cases in which no quantities are supplied, there are three distinct modes of estimating in common use, in each of which the schedule or bill of quantities occupies a different relation to the contract. In the first the actual contract is independent of it, and its only use is to enable men to form a correct estimate of the sum for which they may prudently contract. In the second the schedule is supplementary to the contract: it is a sort of appendix regulating the modification of the contract in certain contingencies, and also supplying the architect with information which is very useful to him during the progress of the work. In the third the schedule is the contract to all intents and purposes. Now as these three modes of estimating have been in use for many years in the largest centres of population, we may reasonably expect by careful consideration of their working to obtain some useful lessons, and this none the less although we may be compelled to regard the existing state of matters as upon the whole unsatisfactory—the existing diversity itself, indeed, is unsatisfactory.

(To be continued.)

THE PAINTED CEILINGS AT ST. ALBAN'S.

WITH reference to the appeal on behalf of the painted ceilings at St. Alban's by the Society for Protecting Ancient Buildings, referred to in these columns last week, Sir Edmund Beckett writes that if the "Society" will take the trouble to read the reports of their own architectural partisans last November or his summary of them in the *Times* on Christmas-day, they will find their secretary's questions fully answered. If they do not choose to do that and to learn what the 'painted' ceiling was which alone is meddled with both in art and substance, they will attend to no further answer now. At any rate, they will have none from the committee."

The Hon. Secretary to the Restoration Committee writes that the letter of Mr. T. Newman Marks shows beyond all doubt that he has not

taken the trouble to come down to inspect the painted ceilings and to see for himself what the committee have really done. "He would find the exquisitely-formed ceiling over the choir of the time of Edward I. has simply been cleaned from cobwebs and dust, that the richly-painted ceiling over the nave as far as St. Cutbert's screen has been most judiciously restored on the old lines, to the delight of all who behold it, and even what remains of the, comparatively speaking, modern distempered ceiling over the rest of the nave (which is not actually rotten) will be retained by Mr. John Scott."

Mr. J. O. Scott writes: "Should Mr. Marks happen to visit St. Albans a few months hence, when the works now in progress are completed, he will, I hope, be gratified to find his wishes on behalf of these ceilings carried out; but he must not on that account take any credit to himself for 'intervening,' for there has never been any intention of destroying them. There are two divisions of the nave ceiling, the whole of which is flat in design. The eastern part, occupying about a third of the length, is panelled, and is very beautiful; but it is well to bear in mind that its beauty is mainly due to the careful restoration of its ancient painting carried on about three or four years ago, this having till then been concealed by some poor caricature of it done in modern times. This fine ceiling will be scrupulously preserved; there has never been a thought of anything else. Probably its panels, which are movable, will be taken down during the work to insure their safety. The western part is not so good. It is quite plain, without panels—in fact, like a wooden floor reversed. A resolution was passed some months since to restore it in oak, using as much of the old boarding as possible; and the contractor has framed his estimate in accordance with this. I fear the proportion of new wood will be very large, the bulk of the boards being of modern deal, and the rest grievously rotten. The intention is to keep as much as we can, but of course we shall only replace the unsound wood. The painting of this part of the ceiling is excessively rude, but turns out to be a rough copy in distemper of the original decoration which we find underneath, and which will be restored, as has been done with such good results in the eastern part. I am sorry that Mr. Marks should call our new roof an 'uncouth monster.' In one sense, the cathedral itself is a monster, and its covering must be in proportion; but if this very straightforward, high-pitched roof, covered with respectable lead, is, in his opinion, 'uncouth,' so must also be those at Westminster, at Salisbury, and at Lincoln; so that, as far as this is concerned, the committee and the public may safely retain their peace of mind."

CHIPS.

The east window of the north aisle of Woburn Church, near Newton Abbott, has been filled with stained glass. The four principal lights are occupied by two tiers of subjects, the upper series illustrating the miracle of the "Raising of Life of Jairus' Daughter," and the lower series the "Raising of Lazarus." The tracery lights, contain a representation of Christ with outstretched hands, regarding His adoring followers, who are placing their crowns at His feet. The work has been done by Mr. F. Drake, of Exeter.

On Friday morning an inquest was held at 30, Thurlow-road, Hampstead, on the body of Mr. Horace Field, aged 56, architect, and district surveyor for Putney and Roehampton, who expired suddenly at his residence on the previous Wednesday. The evidence of Dr. H. Cooper Rose, who had made a *post-mortem* examination, showed that death resulted from fatty degeneration of the heart, and a verdict to that effect was returned by the jury, of which Mr. Carl Haag, the artist, was foreman.

A new chancel and organ-chamber are being added to the church of St. James, Preston, from the designs originally prepared in 1869 by Mr. Hibbert of that town. The chancel is 25ft. wide by 42ft. to apsidal east end, and the organ chamber is 19ft. by 12ft. Longridge stone is used for facings, and in the chancel will be a memorial stained-glass window to the late Alderman Spencer. The contractors are, for masonry, Mr. Lamb; woodwork, Mr. Bamber; glazing and painting, Messrs. Walsley and Co.; and plastering, Mr. K. White. The cost will be £2,500, exclusive of permanent fittings and new pulpit, lectern, and stalls.

The Tyndale Memorial Committee have intrusted to Mr. J. Edgar Boehm the design and erection on the Thames Embankment of a statue of William Tyndale.

NEW PREMISES, 57, NEW BOND-STREET.—"DYBDALE,"
WELLINGBOROUGH.—UNIVERSITY COLLEGE, BRISTOL.—
SCREW SCAFFOLDING.—ST. PAUL'S CHURCH, MAN-
CHESTER.

OUR LITHOGRAPHIC ILLUSTRATIONS.

157, BOND-STREET.

ONE of the most conspicuous drawings this year at the R.A. is that of the above building, of which Mr. Robert W. Edis, F.S.A., is the architect, and we are enabled to reproduce it to-day for the benefit of our readers. The execution of the work was conducted by the proprietor, under Mr. Edis's supervision, and much care has been taken to carry out the architect's designs for the whole of the work, including some costly carton pierre decorations to the large picture gallery at the rear of the premises. This work, and also the mantels, were executed by Messrs Jackson and Son, of Rathbone-place. The carvings throughout are the work of Mr. Frampton, of Camberwell. Besides the Royal Academy perspective we include in our illustration a section of the front.

DYBDALE, NEAR WELLINGBOROUGH.

THIS house, now nearly completed, is built of red Berkshire bricks, with Staffordshire roofing tiles. The whole of the internal fittings, including fireplaces, &c., have been made from special designs prepared by the architect, Mr. W. Talbot Brown.

UNIVERSITY COLLEGE, BRISTOL.

A FEW weeks since we published a double-page view of Mr. Stuart Colman's larger design for the new University College proposed to be built at Bristol. We then gave a general description of his plans, and to-day we illustrate Mr. Colman's smaller design, of which he has sent us the following particulars:—The two-story building consists of a broad central corridor, with the council-room, principal's, professors', secretary's, and men's reading and cloak-rooms opening conveniently from it. It leads on the right to the large lecture-room, which fills the right wing, and forms a prominent feature from the S.W. approach. The small lecture-rooms not requiring apparatus, and the women's reading-room, are placed upon the upper floor. Owing to the rapid slope of the ground, beneath the large lecture-room accommodation is secured for the physical and engineering rooms, opening on to the lower level of the quadrangle, or reached by a staircase contained in the tower on the right hand.

TOWER AND SPIRE, ST. PAUL'S CHURCH,
MANCHESTER.

MR. JOHN O. SCOTT'S only exhibit at the Royal Academy this year is the drawing which we reproduce to-day of the tower and spire of St. Paul's Church, Manchester. The original design for this church included a tower and spire, but this feature has been considerably enlarged upon since the first plans were made, owing to the munificence of a lady who has borne the greater part of the cost. It was finished some few months since, Mr. Collins, of Tewkesbury, having been the contractor. A peal of bells will shortly be arranged in the tower. The drawing is by Mr. Samuel Weatherley. We gave a view of the west front of this church on September 10th, 1875, and another of the interior on September 7th, 1877.

SCREW SCAFFOLDING.

For a description of this illustration see article on p. 581.

FURNITURE AT THE YORK FINE ART
AND INDUSTRIAL EXHIBITION.

IN the BUILDING NEWS of the 9th inst. you gave an account of the opening of this exhibition. I now send a few notes on some of the furniture and kindred exhibits, which are not only numerous in quantity but excellent, as a rule, in quality. On each side of the main hall of the permanent building are arranged buffets of various makes. The first on the right upon entering, is contributed by Appleyard and Sons, of Rotherham. It is of pollard oak, simple and effective, some of the mouldings being stained black. In the back are three panels, painted on a gold ground, with birds and flowers, emblematical of morning, noon and night. Another buffet, also of oak, larger and more profuse in ornament, is exhibited by same makers. The panels of cupboard doors are carved with wheat-ears and grapes, and the back of the upper portion is lined with stamped leather in sage green and gold. There also are painted panels, the largest, at the top, being a hunting scene. The side of a room in Jacobean style, with a buffet and two chairs, are exhibited by Messrs. Marsh, Jones, and Cribb, of Leeds. The mouldings of the buffet generally display much taste, but the panel bearing five female figures in Greek costume is not quite so happily executed as it might be. The next side-board is of a thoroughly different character. The style is a kind of French Renaissance; the parts are few and massive, and the carving is very naturalistic, and in full relief. The doors of the lower portion bear heavy bunches of game. Three large mirrors form the back, the centre being separated from the side ones by female figures, the one holding a bow and the other a fishing-rod, but are not very high specimens of figure-carving. The buffet of Mr. John Taylor, of York, is better worth notice. The arrangements are simple, carving conventional and in low relief. The back is enlivened with panels painted with flowers and buds, upon gold grounds. Crossing the hall is reached a lectern by Harry Hems, made from an oak beam taken from Salisbury Cathedral, the most important feature being four angels with outspread wings in various attitudes of devotion, ranged around the stem of the lectern. The foliage carving is executed with good taste.

The next article of furniture is a cabinet in rosewood, designed by H. W. Batley, and exhibited by Messrs. Ogden and Son, of Manchester. It was awarded a silver medal at Paris last year. It is Jacobean in style with a few traces of Japanese influence, which is characteristic of most of the works produced by this firm. There are no broad surfaces, the whole thing is broken up into small cupboards and shelved recesses with a projecting, quaint, glazed receptacle in the centre of the upper portion, and every part is covered with moulded, carved, or painted ornament.

James Lamb, of Manchester, has an important show. There is a dining-room buffet in brown oak, with chairs of various designs, and panelled wood ceiling for a dining-room. The section appropriated to drawing-room furniture contains two chiffoniers, a what-not, occasional table, &c., which are mostly elegant, but have no special features demanding attention. The side-board exhibited by Messrs. Simpson and Son, Halifax, is fussy in design and of no particular style. The Gothic cabinet, in old English oak

(Mr. J. Lumhey, Leeds), is more quaint than beautiful. The candlesticks are peculiar, being on the one side a bone, at which an uncomfortably-seated dog is looking, and on the other a bit of branch, explored by a mouse, who occupies the attention of an uncomfortably-seated cat.

In the galleries of the temporary building are various compartments devoted to furniture, decoration, &c. Several of those on the south side are not yet fitted up. On the north side a compartment, rather gloomy-looking, is filled with church furniture and fittings, mostly designed and executed by Mr. Knowles, of York. The entrance, formed of organ-pipes, is heavily draped. The light is obtained from three openings filled with stained glass, which form the most interesting portion of the exhibits. The centre light is occupied with a figure of St. Cecilia, seated at an organ in a very constrained attitude, but otherwise well drawn, above her being a small choir of angels. The other lights are Renaissance in style, and adapted to domestic work. The middle portions are occupied respectively with emblematic figures of music and painting. The exhibits of Messrs. Marsh, Jones and Cribb, are of domestic function, the best article being a chimney-piece in oak, refined Jacobean in style. Hunter and Smallpage, York, have various articles of bedroom furniture, of good, but not special, design. Three compartments are occupied by Hummerson Bros., of Leeds, who treat them respectively as a drawing-room, dining-room, and bedroom. The buffet in the first is as pleasing as anything in the exhibition; the design is simple and the mouldings delicate. The shelf of the mantelpiece is a great deal too massive. The bedroom suite in polished pine is generally elegant, but the chairs are not altogether satisfactory. The drawing-room has a very funeral aspect, the woodwork being ebouissed without any lines of gold or colour. The most pleasing article is the centre octagonal table, in Anglo-Japanese style. This compartment would have looked better without the door, which is supposed to be the entrance to it. The style is altogether out of harmony with the furniture, and is not beautiful in itself.

COMPETITIONS.

BLACKBURN.—In a limited competition for a new Wesleyan School Chapel, Blackburn, the Committee have selected the designs sent in by Mr. Miles Aspinall, of Blackburn.

IPSWICH.—Mr. Chas. Barry will visit Ipswich on Tuesday, Wednesday, and Thursday in next week, to inspect the 22 plans sent in to compete for the premium of 50 guineas, offered by the Corporation for the Post-office buildings, and to advise the committee as to their award.

SWINDON.—The School Board recently opened a competition for plans for the first school to be built, one for 250 infants, with a view to the selection of an architect to the Board. Twenty-eight architects took part in the competition, which has resulted in the appointment of Mr. Brightwen Binyon, A.R.I.B.A., of Ipswich, and architect to the School Board in that town.

The Bournemouth Improvement Commissioners received and accepted at their meeting last week the resignations of Mr. C. C. Creeke, consulting surveyor, and for many years town surveyor, and of Mr. G. R. Crickmay, town surveyor. These resignations were tendered in consequence of difficulties connected with the sewage and outfall works now in progress. The commissioners are threatened with litigation by Mr. Stickland, the contractor for the inland drainage work, and are apprehensive of being personally surcharged with £1,100, declared by the Local Government Board Inspector to have been wrongly paid to Sir Joseph Bazalgette.

At the Wesleyan District Conference at Manchester, last week, proposals were approved to erect new chapels, at Silverdale to cost £1,400; at Kirkdale, £5,220; at Llanwrst, £940; at Presteigne, £850; at Colwyn Bay, £1,945; at Rufford, £819; at Earlestown, £5,000; and at Blundellsands (iron) £1,146; also schools at Fairfield, £2,558; at Palmgrove, Birkenhead, £650; and at Penketh (enlargement) £105; minister's house, at Lancaster, £810; and organs at Leatherland, Cranmer circuit, and at Adlington, Chorley circuit.

The Duke of Bedford and Mr. Boehm, the sculptor, are about to present a model of the statue of John Bunyan, erected at Bedford in 1874, to the Baptist College in Regent's-park.

SCREW SCAFFOLDING.

THE following is a description of the scaffolding referred to in my letter on "Building Machinery," which appeared in the BUILDING NEWS of April 25th:—Fig. 1 (see Photolithograph) is a half-plan of, and Fig. 2 a section through the centre of tower, showing the screw scaffolding in position. A A are four scaffold screws, which bear the whole scaffolding of tower, one being placed in each angle of wall. Each screw is shown to work (see Fig. 2) through three nuts, B1, B2, and B3, and has a collar C, carrying a saddle D for the support of the ledgers E F and framing, from which the workmen's platforms, or scaffolds G, are suspended by wrought-iron slings, H. The wheels J of the bearers to outside scaffold travel up the face of the wall as the scaffold rises. Guard rails, K, are fixed where required, to insure the safety of the workmen employed.

In proceeding to fix the scaffolding, where the scaffold-screws are to work in the wall, all that is necessary is to place the screws A A in their proper position in the wall whilst the foundations are being put in, then plumb and build round them, clamping two of the nuts, B1 and B2, on each screw at the same level, and at the required distances apart. If 2' 6" of wall is to be built for each lift of scaffold, the nuts will require to be placed every 2' 6" in height. The screws should next be turned until all the saddles, D D, are standing on the same level; the overhead framing, ledgers, and platforms should now be placed in position, the nut B3 clasped on where shown, and the work of building from the scaffold begun.

If the platforms G G are placed about 12in. below the top of the wall then built, sufficient space will be left between the top nut, B3, and the collar C to allow of building up to the line of L, as required before raising the scaffold. The scaffold platforms will then be standing at about the best height for effective work, as the workman will, by such an arrangement, always be walling from just below his knee to about the level of his elbow, thus avoiding undue stooping and over-reaching.

When the 2' 6" of wall has been built all round, the workmen, whilst standing on their scaffolds, turn the screws A A (by a simple arrangement at the collar C), and raise the scaffolding, walling materials, and themselves as well, a height of 2ft. 6in. The foot of the scaffold screw will then have passed the bottom nut, B1, leaving it lying loose in the wall. This nut must then be drawn out of the wall (a hole opening to the inside being left for this purpose), and clasped on to the scaffold screw at the level of L, making it thus a top nut. When, after the next lift of scaffold, the foot of screw has passed up through nut B2, this nut, in its turn, is lifted up and made a top nut; and so on successively until the full height of wall has been built. It will thus be seen that a screw never rests in less than two nuts. As the screw by this system travels up with its scaffold, the same screws will do for any height of wall. There is no necessity to clear the platforms previous to raising. Before commencing to plaster the nut holes in the body of the walls are filled up, and the holes left by the screws are well grouted.

For "cleaning down" the work the outside platforms can be lowered as required from the projecting ends of ledgers.

The scaffolding screws can be used in three separate ways:—

- 1st. Working in the body of the wall.
- 2nd. Against one of the faces of the wall.
- 3rd. Independent of the wall.

Figs. 1 and 2 show the first method, where the screws are seen to work through the body of the wall.

By the second method the screws are supported on iron elbows projecting from one of the faces of wall, somewhat after the manner of No. 3 arrangement.

Figs. 3, 4, and 5 are a plan and side and back views respectively of uprights for supporting the scaffolds independent of the wall, as per third method. These uprights are made of three thicknesses of deal (bolted together from time to time as the scaffold rises), half-lapping as shown. When the scaffold platform has been raised to about the position indicated on Fig. 5, the upright is heightened by bolting on fresh lengths, as shown by dotted lines. M, M, are iron elbows bearing nut rests, N, N, which carry and keep the nuts, O, O, firmly in position.

When the scaffold has been screwed up the bottom elbow, with its nut-rest and nut, is taken off and raised to a higher part of upright, and so on, as in the case of screws working in the walls. The screws, in this case, can be turned by applying a handle to the top of screw, at P, by the workmen standing on the scaffold.

In the church where this system of scaffolding was employed, screws were placed in the aisle walls at Q Q (see Fig. 6) for the support of one end of aisle ledgers, the other end of ledgers, together with the whole of nave scaffolding, being supported by uprights, R R, fixed about 3ft. from nave arcading, to allow of working-space between the upright and the nave wall. When the walls of aisles had been built to their full height, the aisle ledgers were detached from the nave ledgers, and the nave scaffolding screwed up, stage by stage, for the construction of the nave arcading, clerestory walls, and gables. When no longer required for walling and roof-fixing purposes, this nave-scaffolding was used by the plasterer and the decorator. After first coating the ceiling, all that was necessary was to screw down the scaffold platforms, stage by stage, whilst the walls were being first coated, and screw them up again for the second and finishing coats of plaster.

Figs. 7 and 8 indicate how this system may be applied in the case of an ordinary building in a thoroughfare. S S are uprights for four screws, which, in this case, carry the whole scaffolding. Where the screws are placed at long distances apart, it may be necessary to truss the ledgers or scaffold-bearers, and where the builder wishes to work with a minimum number of screws, trussed bearers will naturally suggest themselves. To prevent the possibility of brickbats and building debris flying out into the roadway, I have shown a screen along the front of the building suspended from the scaffolding. This screen, which may be a kind of rope netting, will uncoil as the scaffold rises, see Fig. 8. If the whole of the material for a work of this kind is raised in the interior of the building, and the outside scaffold platforms used for the purposes of setters merely (and not for walling materials), there need be but slight inconvenience, and little or no danger, experienced by the street traffic whilst building operations are carried on.

As to the covering in of these scaffolds, reference to the sections will show that all that the builder requires to do for this purpose is to stretch tarpaulins or covers over such portions of the ledgers as will afford the necessary protection to the working platforms and walls. These coverings may be placed in position when the scaffolding is first fixed, as they add but little to the weight, interfere in no way with the raising operations, and go up with the scaffold without further attention or alteration.

There is no valid reason why the whole operation of building should not be carried on under cover, and the "waller" be placed in as good a position for doing his work as the "stonedresser."

The arrangement here applied to scaffolding could be made available for the extension of existing buildings by raising the roofs entire, and adding to the walls as the roof rose, in place of the tentative methods now resorted to when "roof-raising" is practised.

JOSEPH J. LISH.

MR. STREET ON THIRTEENTH CENTURY ARCHITECTURE.

AT the meeting of St. Paul's Ecclesiological Society, held on Wednesday evening, at the Chapter-house of St. Paul's Cathedral, the Dean Milman in the chair, Mr. G. E. Street, R.A., delivered the following address on "The Church Architecture of England during the 13th Century." Numerous photographs and plans were hung on the walls of the room, and the lecturer made on a blackboard rapid illustrative sketches of the sections of mouldings, the grouping of columns, and the traceries and cusping of fenestration as he proceeded. Mr. Street said:

In speaking to you this evening, I shall venture to assume that the object with which you are all gathered is simply that you may obtain some rudimentary information on the

subject of the architectural art of the 13th Century, and if in doing this I am almost too simple for some among you, I fear I may still be too technical for others. What I aim at doing is to enable you, as far as it is possible to do so in one short lecture, to realise for yourselves the cause of the development of English architecture in the 13th Century, and next to put you in the way of grouping and classifying the ancient examples which you are able to examine with some degree of precision and accuracy.

I confine myself to-night almost entirely to English architecture for several reasons:—

1st. It is ample for our time.

2nd. It is, I think, the best architecture of the period; and

3rd. It has such distinct characteristics as to make it necessary to treat it by itself.

In earlier times this was not so. Our earlier architecture was Roman in its origin; our Transitional still Romanesque in almost all respects; and in the 13th Century it was that architecture burst out with what was really a new invention—a new style.

One needs not to dilate on the 13th century and all its glories—the age of Dante and of the great group of Italian artists of all sorts who surrounded him, Giotto, the Pisani, Memmi, Buffalmacco, Arnolfo, and others; in France, the age of Philip Augustus, and of the grandest churches in that great country; in England, the period which is occupied by the reigns of John and Henry III., which saw the erection of Salisbury, Wells, Lincoln, York, Fountains, Whitby, Beverley Minster, and much of St. Alban's, not to mention others; in which Magna Charta was signed, and the foundations laid of all our subsequent greatness and prosperity; in which, finally, English art arrived at a perfection never since approached.

You have been told by a previous lecturer about the Transition. In it there was more respect for the past than hope for the future. The pointed arch was used because it was useful, not because it was liked. The problem in construction, which its use involved had not been realised or worked out. The art was essentially one of rest and quietness.

Amongst the reasons for the development of the new mode of building nothing was more important than the adoption of groining; when once this was introduced the builders perceived that the pointed arch was the best suited for their purposes. With the circular arch groining could be, and was used, but the junction of nave and aisle was awkward, the larger arches being necessarily stilted to suit the smaller ones, and the construction was weak. Thus it became almost essential that the arch should be pointed. Then the thrust of the arches had to be manifestly resisted, and this provision for thrust led to the introduction of the buttress, and the more scientific disposition of the masses.

Before the 13th Century all the principles of architecture were founded on Classical traditions. The arch, it is true, was used, but it was the arch at rest. It appeared to exert no lateral thrust. The piers were enormous, the walls very thick and no buttresses, and the weight and the thrust of superincumbent work was as weak as possible, distributed all over the length of the wall face. In the 13th Century all this was changed. Men discovered the real use of the arch. The pointed arch had been used in the East at a much earlier period. In Europe it was introduced and used in the latter half of the 12th Century; but only because it was convenient. How it came to be invented would in any case be a merely antiquarian question; but how suddenly the discovery of its proper use revolutionised our art, and that led at once to the invention of a new style is the real interesting fact in the whole history of architecture. All other styles may be said to have been slowly developed by patient steps, each being little in advance of the last. Here we have a sudden mighty change in the whole practice of the art following immediately on what was in truth as distinctly a discovery as are any of those great inventions which in our century have changed the whole current of labour in so many ways, as, e.g., the locomotive engine and the electric telegraph.

The 13th Century architecture is not in any proper sense a mere development. Its authors knew indeed what had been done in their earlier years and by their fathers. Their merit was that they realised at once in a practical way the proper consequences of the use of the pointed arch. What were these? (1) Weights were

gathered together, carried to the ground in part, and in part distributed by arches to other piers or buttresses. (2) Walls were no longer continuous masses of vast thickness. The wall proper was a thin connecting link between the buttresses which received the weight from above brought to them by arches and flying buttresses. (3) The construction was everywhere displayed. Men's delight in it made them show it; and henceforth the ornament followed the construction so closely as to make it almost a canon that all ornament should be used with a view to emphasising the constructional lines of the design. The result of these three principles or rules was, one may almost say, a necessary one. Architecture was, as it were, suddenly vivified. Where before all was at rest, suddenly an active life pervaded every stone. The building became almost as full of life as a human being. Each part had its work to do, and its shape, its position, its section was contrived expressly to enable it to do it in the best way. The essential difference between all earlier architecture and that of the 13th Century was, in a word, that in the latter there was from beginning to end thrust and counter-thrust in every part of the wall. From the base to the top of the highest pinnacle, every stone may almost be said to have had its work to do. Masons and architects had been skilful and able up to a certain point before. They had laboured to give decorative effect to their work by a profusion of carved enrichments; but they had known little, if any, scientific power. Within a few years the same men and their children have become transformed into workers so skilful and so scientific that every portion of their work has been touched by a warm breeze of refinement which presents us with the most delicately beautiful results that have ever been seen in the work of architects in any age. For, observe that all later changes were again, as before, merely developments. There is no difference in principle between 13th century and 14th, or between 14th century and 15th, and the only radical changes since the 13th century have been the determination of the Renaissance builders to forget that such a thing as a pointed arch had ever been constructed, and in our own days the determination of mankind in general that solid building of any sort was unnecessary, and that arches were inconvenient because they were in a sense costly.

To-night there is hardly time to occupy you with the question as to exactly when and where this great development arose; most of us would concur in allowing to France the greater share of the honour. In England one of the earliest examples of radical change in style is that to be seen in the choir of Canterbury Cathedral, the work of a Frenchman. But the distinctly French style of this church—the style of the Isle de France—had curiously little influence on architecture elsewhere in England. And there is more general likeness between the buildings of Normandy and England than between those of Normandy and the Isle de France.

Let us now go on to the examination of our subject in detail; and first, let us give a few dates. Most of the work embraced in this style was executed between the accession of King John in 1199 and the death of Henry III., 1272. Of the Temple Church, the choir was consecrated in 1240, in presence of Henry III. Of Westminster Abbey, the first stone was laid in 1245 of the choir and transcripts, and it was completed in 1269; Stone Church, Kent, and St. Mary Overie, Southwark, were completed about the same time; Salisbury Cathedral was built by Bishops Poore and Bridport 1218-1258; Wells Cathedral, 1225-39; York Cathedral, 1227-40; Fountains Abbey, 1205-46; of St. Alban's, the West end, 1195-1214; and the East End, 1257; and Lincoln Cathedral, 1232-35. Of this period about all the most exquisite of our abbeys are illustrations, as e.g.,—Netley, Beaulieu, Whitby, Rievaulx, St. Mary's, York; Lanercost, Dunstable, Bisham, Tintern, Fountains (East end); Easby, Finchal, and in Scotland, Dryburgh, Pluscardine, Elgin, New Abbey, Jedburgh, and Glasgow, and Ireland, Christ Church and St. Patrick's Cathedral's, Dublin; Kildare, Kilkenny, not to mention many others. Observe here, that all the dates I have given are of the first half of the century. In point of fact, the style to which I must direct your attention is seen in some of its earliest efforts, fairly complete in the last twenty years of the 12th Century, and by the end of the reign of Henry III. had

become so changed as to be in truth a different style. It is only in a rough and arbitrary way that one can talk of the art of a century, and it must be always as of that which most distinguished the century, rather than of that which was practised throughout the whole course of it. There was too much life and change to make any other treatment of the question possible. Of the examples which you can most easily study on the spot are, of course, Westminster, the Temple Church, St. Mary Overie, the Archbishop's Palace Chapel, Lambeth; and in the neighbourhood of London, St. Alban's Abbey, Stone Church, Rochester Cathedral Choir, and Dunstable Priory.

If I do not at every turn refer you to examples, it is because I know you will visit them and examine them for yourselves; for this is part of the excellent programme of our Society.

A few words as to how you should do this. Observe, wherever you go, the following points in every building:—1. Ground plan and plan of groining. 2. General character of design. 3. Character of piers and arches, and mouldings. 4. Character of traceries and areades. 5. Special features of construction. 6. Furniture, monuments, and details generally. And, to enable you to do so, let me tell you in a few words what you will usually find and should look for in such examinations.

1. Ground plan.

Most Romanesque and foreign plans had apsidal terminations. Canterbury had one, but copied from Sens; Westminster apsidal designed in England, but under somewhat French influence.

English prejudice was, however, against the apse, and it is very rarely introduced in work in this country. Glastonbury, "a well of English undefiled," is square ended, and the influence of this abbey was very great. All the churches in the Irish Pale are square-ended. A great number of 12th Century apsidal east ends were destroyed in the 13th and 14th century in order to make room for square ends,—sometimes under difficulties, as e.g., at Winchester and Gloucester, where the crypts remain apsidal although the square structure is altered. Stone Church, which was obviously built by the same men as Westminster, is square ended. In fact apsidal terminations after end of 12th century were very rarely constructed in England, though many were pulled down.

The ground-plans of churches within your reach for study afford all that you can desire in the way of illustration. In Westminster Abbey you have a very English version of a French chevet, as the apsidal end with its aisle and chapels is called. You need not be told how beautiful its general effect is. But if you will examine its ground plan you will see how extremely scientific it is in every arrangement, and how it grew out of the necessities of the case. Agreed that your central roof must be lofty, properly lighted, and covered with a stone vault, and the apsidal form makes it necessary to provide buttresses radiating from the centre. In order to provide aisles round the apse these buttresses have to be carried on arches, and thus become flying buttresses, and the spaces between them become available for use as chapels, opening out of the aisle or procession-path.

(To be continued.)

THE HISTORY AND AESTHETICS OF ARCHITECTURE.—IV.

MR. STATHAM brought his course of popular lectures on Architecture, at the Royal Institution, to a close on Saturday afternoon, with a description of the development and leading features of the Gothic style. The address was illustrated by photo-lithographs distributed amongst the audience, and by numerous coloured large-scale drawings of typical details in each phase of the style, which were hung upon screens.

There was no period, the lecturer said, at which so much activity in building prevailed in the north of Europe as at the beginning of the 12th century. One very curious reason for this sudden commencement of large and important buildings was that the world had safely passed through the year 1000, in which it had been generally expected to come to an end; but another and less vague impetus to build was the frequent adoption of a conventual life, especially in France during the reign of Louis VI. The needs of monastic establishments effected a transformation in modes of building, and their remains

now formed the chief monuments of the style. The buildings of the Cistercian order were amongst the noblest examples of pure and simple work of Early Gothic architecture. They had monasteries at Furness, Fountains, Kirkstall, Valle Crucis, and many other places, where they secluded themselves from the world. Their buildings depended almost entirely for their beauty upon fitness and appropriateness, and hardly at all upon mere ornament. The general plan of a Cistercian monastery was exhibited and explained. On the south side of nave of the long, cruciform church abutted the cloister, which, so far from being but an ornamental adjunct, was designed as a mode of communication between the church and the various rooms, the refectory on the south, the frater and the chapter-house and day-room on the east. Along the west side was a long room, which had been proved by the investigations of the late Mr. Edmund Sharpe to have been the domus conversorum, or place where the lay brethren who lived without the convent assembled. This room was usually divided by a double range of columns down the centre, and consequently vaulted in two spans. The same general plan was generally followed in monastic establishments. On comparing the vaulting plans of a Roman, Romanesque, and Gothic building, a great difference would be seen. In the first, half-columns were placed against the outer walls, and other columns abutting on the inner sides of the walls, the lines of vaulting passing diagonally across. The external columns became square pilasters in the Romanesque and style, and the internal columns were brought away from the walls. In the Gothic building the piers kept much the same position as in the Romanesque, but the walls were broken up into sections, and these were turned edgewise, the better to resist the thrust. In this alteration in plan, caused by the pointed arch, was the distinctive difference between Roman and Gothic architecture. A key diagram of the features of Gothic architecture was explained, the lecturer enforcing the fact that repetition was an essential quality of Gothic architecture of every period; each arch and its surroundings formed a section of a design, each part of which could be studied separately. The mode in which the blank space on the internal wall, caused by the abutment of the aisle roof, was occupied by the triforium arched was instanced as an example of logical and effective ornamentation, and another was the addition of flying and solid buttresses to resist the outward thrust of the vaulted roof, and convey it to the ground. In French cathedrals, in which the walls were carried to greater heights than in this country, the buttresses became very towers, and seemed as it were like a series of giant hands clasping the building, and with their outstretched fingers forcing the walls inwards. Although the internal vaulting was of stone, the outer roofing was of timber, because it was found difficult to make the joints of masonry watertight; had the Gothic builders known the use of Portland cement, the mode of roof construction might have been different. Having described in detail the chief features of a Gothic church, the lecturer went on to explain the process of development of the style. The difference between the Norman and Transitional styles was exemplified by means of bays of each placed side by side, the enlarged window space, the introduction and uncertain use of the pointed arch, and the peculiar nicking of the abacus of the capital being indicated as characteristics of Late Norman work. A series of four capitals sketched inside the western portal of Peterborough Cathedral were illustrated, the lecturer remarking that whether carved by one artist or by four, they furnished perfectly clear examples of the progress of Gothic foliage. In this Transitional period the carving of leaves was still straight, stiff, and sturdy; the piers were square and very thick, and attached to them were small, circular shafts, for the arches were being broken up into several members. The next period of Gothic was known as the Lancet style from the form of its window openings. In it the pointed arch was universally adopted, but the round form was retained for the triforium to inclose coupled pointed arches, above which was a quatrefoil, affording the first suggestion of tracery. The style depended upon construction, and not on ornament for effect; indeed, almost all the finest architecture in the world was independent of mere decoration for beauty. When a building was plastered over with ornament, it was an, almost certain sign

that the true object of architecture was forgotten and that the builder was attempting to cover his want of constructional knowledge. The whole interest of a 13th Century building consisted in the frank and perfectly commonsense way in which its purpose was expressed; the clerestory windows to admit light to the central space, the flying and aisle buttresses to support the roof and give massiveness to wall, and the very base courses of plinths forming the groundwork of the whole design, as well as performing a constructional office. The carving of foliage flowed in curves, but was still marked by its stiffness. An effect of decoration of the arcades was often entirely produced by the contour of the mouldings and the consequent alteration of light and shade, without the introduction of a single sculptured leaf or flower. The piers had now changed in form from a square to a lozenge on plan, and several shafts were now attached to them, and that not alone at the inner angles. This pure style was succeeded by two forms of Decorated architecture, the Geometrical and the Curvilinear. More ornament was employed; the windows were filled with tracery, the lines of which flowed one into the other; crockets were added to buttresses and canopies, and capitals were surrounded with a band of foliage, which no longer appeared something growing out of the head of the column, but an applied ornament. The foliage was less conventional and more varied in character. In like manner bench ends and similar features were covered with carving, and a small ornament known from its form as the ball-flower was used everywhere—sometimes with good effect, but often too profusely, and in some districts carved upon every portion of the window mullions and other surfaces. The lines of mouldings were chiefly in half-rolls. As the tracery was developed, the window space was increased; it was absurd to regard Gothic as a style which sought to exclude the light, for in no mode of architecture were the window openings so large in proportion to the masonry as in the later forms of Gothic. A further development of the style was distinguished as the Rectilinear period. There was now a great predominance of horizontal and vertical lines in place of the springing forms and flowing curves that had preceded this phase of the style; the arches were now struck from four centres and were flattened at the crowns; right angled lines defined every window and its parts, and panelled surfaces were general. The triforium was reduced to a mere passage behind the piers. Throughout the building there was seen a tendency to hard straight lines, rather thin mouldings, shallow carvings. Where foliage was used it was dotted on to the capitals in a conventional and simple manner, and often it was omitted. The whole seemed designed for saving trouble to the designer and workmen in all but the vault. While, however, this tendency to reduce everything to right angles was developing in this country, singularly enough, French Gothic was becoming more and more flowing with its lines, till it became flame-shaped in character; hence its distinctive name, Flamboyant. In France alone the outline of the basilica was more strictly followed at the east-end, which was usually rounded off into an apsidal form, and surrounded by chapels, while the typical English east-end was at every period square. To this broad rule there were exceptions, and at Westminster Abbey might be seen a building built very much under French influence, and after their mode. But he must return from these details to describe the development of the arch and vault. Last week he had shown how the flat soffit of the Roman arch became broken up when smaller materials were used, and the influence the change had on the form of the columns from which the arch sprang. The rich effect this multiplication of recessed members gave in Transitional Architecture might be seen from a drawing of the west front of Tewkesbury Abbey. Another step was to have a square abacus beneath which the capitals and round shafts were continued, and it became necessary to break the abacus into projections to assimilate with the parts above and beneath. A further development was to round off the abacus to follow the general outline of arch soffit and grouped shafts, and afterwards the jointing was arranged to fall into the centres of the hollows,—a characteristic of the best work—and at length every sharp angle was cut off, and all the mouldings were worked in the chamfer plane. The pier was gradually getting elongated, and was being turned with

its narrow edge towards the church. But what effect had these changes had upon the vault? The first step was to mark the main lines of the crossing vaults by projecting stones. The next was to add more ribs, intermediate ones being stretched across the centre of the vaulting space. A result of this was that it was found that the arch would stand on the ribs alone; thus, instead of two arches, the vault became a collection of arched ribs. The surface masonry was no longer used for support, and so its joints were arranged for effect instead of to afford the greatest strength; they were laid in horizontal courses, and not placed at right angles with each other. Greater elaboration followed, and cross or lierne ribs were worked upon the surface so as to cover it. The ribs did not spring at equal distances from each other, and, to overcome the awkward appearance, the boss from which they were projected was enlarged, and a step made towards the fan-vault. At length the boss became an inverted cone, and the ribs were caused to radiate at equi-distances around it, and at the same angles. The vault thus became symmetrical, completely consistent, and logical in expression as well as purpose. But the real construction of the vault had again become completely changed, and had reverted to its earliest principle, for, as in its first conception, the vaulting surface was again supreme and the ribs were but applied ornaments. Though the result when placed side by side with the original form was so different, yet the progress of its development was perfectly natural. He had now traced Gothic to its fullest development. More and more ornament was added, and it became constructionally weaker and weaker, and at length was abandoned in favour of a revival of older styles. It would be seen that the course of lectures now brought to a close had taken them from Greek to Gothic. As far as European architecture was concerned, there were but two styles, Greek and Gothic, consistently constructed on one principle. They had examined into the principles governing Greek, Roman, Romanesque, and Gothic architecture, and had traced the steps of their progress, and they had seen that the latest development of the last-named style, although totally different in form, was lineally descended from the Greek. There was a lesson to be learned from this study of the expression of architectural principles applicable to the present day. At the time of the study of ancient literature there was a revival of architecture, and for the first time, instead of developing existing ideas in building, people began to suppose that the best mode to improve architecture was to imitate what had been done before. No longer was a man frankly to build as his needs and tastes suggested, but he was expected to follow what some one had done, as was supposed admirably, many years before. In Renaissance work the lecturer would admit he could see much that was exceedingly interesting and suggestive, but the old principle of work was departed from. This imitation of the past had since taken many forms; during the present century they had seen a revival of Greek, of Roman, of Gothic, and lastly of the style known as Queen Anne, a new combination made in the Renaissance period, when the Greek forms as corrupted by the Romans, then as modified by the Italians, were next altered by the Dutch and then, by the force of political circumstances, brought into England. In conclusion, Mr. Statham expressed the hope that the lectures had shown that architecture was worthy the attention and study of educated people, and what was logical and what inconsistent building. He had not tried to show a series of pretty pictures of buildings, but to exhibit their constructional anatomy and typical arrangement, and, in the words of a French author, if he had been dull they might be sure he had desired it.

THE IMPROVEMENT OF DUBLIN HARBOUR.

At a meeting of the Institution of Civil Engineers, on the 20th May, Mr. Bateman, F.R.S., President in the Chair, the paper read was on "The Improvement of the Bar of Dublin Harbour by Artificial Scour," by Mr. John P. Griffith, Assoc. Inst. C.E.

The primary object of all early engineering efforts connected with the Port of Dublin appeared to have been to provide a safe approach for vessels to the city. With this in view the Great

South Wall was constructed during the 18th century. The rivers Liffey and Dodder, discharging into the sea at the head of Dublin Bay, flowed over extensive strands laid bare at low water, and the channel cut by the rivers was used by vessels entering the port. The Great South Wall was built to shelter this channel from southerly winds, and also from the encroachment of sand. When completed, it accomplished to a great extent the objects looked for by its designers. Portions of the channel up to the city were still, however, very shallow, and attention was also drawn to a shoal beyond the extremity of the new wall, known as Dublin Bar. This bank stretched from the north side of the bay across the entrance to the harbour in the form of a hook. The deepest water for vessels was round the end of this hook, but across the bank, in a direct line to sea, there was only a depth of from 5ft. to 6ft. at low water of spring tides. At the beginning of the present century many eminent engineers and naval officers were consulted respecting further improvements. Captain Bligh recommended a wall along the north side of the channel; Sir Thomas Hyde Page proposed a similar wall, and the formation of an island on the bar; while a proposal to construct an embankment or wall extending from the north shore towards Poolbeg emanated from the Corporation for Preserving and Improving the Port of Dublin, better known as the Ballast Board. Mr. Rennie, at that time considered the highest authority on the improvement of harbours, prepared an elaborate scheme, but he predicted little likelihood of much improvement on the bar. He expected an increased depth of 3ft. of water as the result of an estimated expenditure exceeding £655,000. To provide a better approach he considered it essential to construct a ship canal from some point on the adjacent coast, where deep water might be obtained, and finally recommended this entrance to be close to the present site of Kingstown Harbour. Mr. Rennie's estimate for this work was £489,731. From 1802 to 1819 the question of the improvement of the bar appeared to have been in abeyance. Probably Mr. Rennie's scheme, from the large expenditure it would have involved, and the smallness of the results anticipated, tended to deter the Government from advancing the necessary funds for any particular scheme. About 1819 the Ballast Board found themselves in a position to carry out their own project of a wall or embankment from the Clontarf shore. Its object was to protect the harbour on the north side from the encroachment of sand, to shelter it from northerly and easterly winds, and to direct the tidal and river waters in a fixed channel across the bar. Before, however, beginning this work, an accurate survey of the river and bar was made by Mr. Francis Giles. Under the joint direction of Mr. Giles and of Mr. Halpin, the engineer of the Ballast Board, the rubble embankment, now known as the Great North Wall, was constructed, extending about 9,000ft. from the Clontarf shore, its extreme end being about 1,000ft. north of Poolbeg Lighthouse. Over 5,500ft. of this wall rose above high water, the remainder being below that level, and the extreme 2,000ft. only reaching on the average half-tide.

During the first half of the ebb, the tidal and river waters running out of the harbour flowed partly over the submerged wall and partly through the harbour entrance, between its termination and Poolbeg Lighthouse. As soon, however, as the tide fell below the level of the wall, the water contained within the two great piers of the Port passed through the contracted entrance at Poolbeg. The velocity of the stream was thus greatly increased, and a channel had been formed across the bar with 16ft. at low water of spring tides, where, in the year 1819, there was only a depth of 6½ft., and there was reason to believe that a still further increase might be looked for. As the improvement of the bar appeared to be due to the water discharged from the harbour during the second half of the ebb, any addition to the tidal capacity of the harbour below that level might be expected to produce a corresponding increase in the depth on the bar. Such an increase in the tidal capacity of the harbour was actually taking place by the lowering of the North Strand, the result of dredging ballast and the wasting away of the bank.

The consideration of the difficulties overcome in the improvement of the approach to the Port of Dublin naturally led to the inquiry, what

were the dangers which beset the maintenance of the deep water channel across the bar? These might be briefly summarised as reclamation within and outside the harbour. Reclamation inside the harbour would be dangerous as an encroachment on the scouring capacity of the harbour. Reclamation outside would result in the reduction of the area upon which sand entering the bay was at present deposited, would tend to drive the low-water mark rapidly further out to sea, and greatly endanger the channel across the bar.

PAINTINGS ON CHINA.

AT the Art-Pottery Galleries of Messrs. Howell and James, 5, Regent-street, Pall Mall, a very choice exhibition of paintings on china are now on view, which we have had an opportunity of inspecting. The works are chiefly by lady amateurs and artists, and display a variety of design and handiwork of considerable merit. One of the special awards for ladies—the gold and silver medal presented by the Crown Princess of Germany, and the Princess Alice prizes—consisting of silver and enamelled badges, has been awarded to Viscountess Hood for a plaque with a figure painted upon the old Willow pattern. The workmanship is of excellent character if we cannot commend the design. Miss Edith Hall's designs, which have received the Princess Alice prize, are marked by considerable taste. One of the plates, numbered 12, shows a conventional treatment of the daffodil, the flowers of which are ranged radially from a dark green centre, it has a scalloped border, the ground being white. No. 25 shows a blue-green margin with wild roses and figures very delicate in the handling. No. 18 is another plate with lily pattern on a blue ground exceedingly pleasing in the arrangement, the flowers being disposed of hexagonally in the centre of plate. Miss Ada Beard's panels in china, for which the prize of H.R.H. Princess Christian of Schleswig-Holstein has been awarded, are painted with much delicacy upon cream or grey grounds, and represent lilies treated naturally. Nos. 2 and 4 are remarkably fine patterns, Persian in character, with leaves and birds, conventionalised, dark blue upon white, designed by Sir H. Rawlinson, a well-known authority in this branch of art. These plates have received the Countess of Warwick's prize. In one of the plates long indented leaves are introduced round within the border, the directions of which are curvilinearly arranged, not radially, from the centre. Nos. 14 and 20 are exquisitely painted plates, by Miss Everett Green. On one the ground is salmon-toned, upon which tomatoes are painted, the birds being drawn in the Japanese fashion. "Is he Dead?" is the title of the second, showing parrots upon a branch looking upon a fallen comrade. The designs for heads are interesting. Mr. Percy Anderson's "Classical Head" (No. 1), painted as a plaque framed, is masterly in composition and outline upon a buff ground. The painting is flat and thoroughly in keeping with the material. As the work of a gentleman amateur, the prize was not awarded. Lady Nicholson's plaque (No. 5) shows some very charming handling of a girl's face. In the ornaments, birds and flowers, No. 26, "Under the Mistletoe," by Mme. Camille Moreau, is a striking example in relief; No. 17, "Chrysanthemums," and Miss E. Lock's "Cardoon Thistle," are also tasteful productions. In an upper gallery, are to be seen many striking examples of china painting by professional artists. We notice particularly a panel, framed in an ebony frame, as quite a finished picture of fruit and flowers. The blue jars, colouring and drawing, are all excellent; the one objection we have to make being that it imitates too closely a painting on canvas in its depth of tone and finish. Miss Ada Hubbard's series of plates, in a frame, upon which flowers are painted after a Japanese manner, are well worth the £10 10s. prize that has been awarded it. Silver medals have also been won by Miss Linnee Watt (233) and to Miss Florence Lewis (265); the latter is a study of chrysanthemums in a pleasing harmony of colour. In the heads we notice Nos. 287 and 289, two very cleverly-conceived studies, classical in spirit, by Miss Phené Spiers, one entitled "Diana Vernon" and the other "Helene." Both are excellent in drawing and colour, the borders are quiet and graceful, and the designs are worthy the taste of this lady artist. We cannot pass Nos. 292 and 295, by Kate Hammond, both exceedingly clever in conception and

colour; nor a terra-cotta bust of Sir P. Cunliffe Owen, K.C.M.G., in which the features have been modelled with considerable truthfulness. Those interested in china painting may spend a pleasant hour in the extensive galleries of Messrs. Howell and James.

BOOKS RECEIVED.

The Student's Text Book of Electricity, by H. M. NOAD, revised by W. H. Preece (London: Lockwood & Co.) will be found a really useful and trustworthy guide by all desirous of studying a science which at the present time bids far more than any other to modify and change the conditions of our lives and habits.—*Electric Lighting and its Practical Application*, by J. N. SNOOBRED (London: Hardwicke & Bogue) is especially of value to those anxious to know something about the practical application of the electrical light, as the work of one who, as his evidence given before the Parliamentary Committee has shown, has done more than anyone else to bring down to the comprehension of ordinary people the cost and merits respectively of the electric light and other methods of artificial illumination.—*The Secret of a Clear Head* by J. MORTIMER GRANVILLE (London: Hardwicke & Bogue), is a pleasantly written treatise, in which the moral and physical conditions necessary to the preservation of health and intellect are expounded.—*The Controversy on English and American Locks*, by HENRY W. CHUBB (London: Chubb and Son), is a reprint of the principal letters and articles which appeared in our own and other journals a month or two back. The controversy originated in a letter sent to the *Times* by Colonel Wrottesley, inclosing one from Mr. James Hill, of Upper Thames-street. The facts put forward by Mr. Hill in that letter soon brought down upon him attacks from all quarters. The letter written by Messrs. Chubb and Son, which appeared in this journal on January 17, was hardly necessary to convince anybody at all conversant with the matter that their position and reputation as one of the leading lockmaking firms of England was in no way compromised by anything Mr. Hill had published; indeed, that gentleman especially mentioned them as one of the exceptional lock firms of this country. Still it did good, if only by enlarging the field of controversy, and the very fair selection now made and published from the subsequent correspondence will do more, by placing before the public the best utterances on each side of a discussion which was undoubtedly one of importance, and which Mr. Hill has probably had no reason to regret that he originated.—*The Softening and Purification of Water* (London: F. H. Atkins & Co.) is a pamphlet full of useful information and hints of that most important subject the supply of pure water. The experience gained by its authors is placed before their readers in a practical and intelligible manner, and will doubtless aid many house-owners and builders in their efforts to obtain that primary necessity to health and comfort, pure and soft water.—*Illustrated Catalogue of Cow-house and Piggery Fittings* (London: St. Pancras Iron Work Co.), is an exceedingly useful little pamphlet. Altogether apart from the special merits of the appliances described, which are manufactured by the St. Pancras Co., and about which there is no need to say anything here, some valuable hints as to the planning and arrangement of dairy buildings may be gathered.

The Local Board of Cirencester last week accepted the tenders of Mr. F. Crockam, of Starcross, Devon, amounting together, as reduced, to £8,047 10s. 10d., for the execution of sewerage works in two contracts, according to the plans prepared by Mrs. R. B. Grantham and Sons, civil engineers, of London. At the same meeting Mr. William Bundy, of Old Kent-road, London, was appointed clerk of the works at a salary of £1 per week.

The Prince of Wales, accompanied by the members of the Metropolitan Board of Works, will open Lambeth Suspension, Vauxhall, Chelsea Suspension, Albert and Battersea bridges free from toll tomorrow (Saturday).

The extensive furnishing premises of Messrs. Atkinson and Co., in the Westminster Bridge-road, comprising eight houses, have been remodelled and refurnished. The works, now almost completed, have been carried out by Mr. Nightingale, from the designs of Messrs. Giles and Gough.

Building Intelligence.

ALLERTON.—The new church of St. Peter, Allerton, near Bradford, was opened on Sunday. It has been erected from the plans of Mr. E. P. Peterson, F.S.A. It is of the style prevailing about the middle of the 13th Century, and is simple in treatment. The edifice is not of large size, and is without side aisles. The tower at the west end of the building is flanked on one side by the entrance porch, and on the other by the vestry. This tower is 71ft. to the embattled parapet and about 100ft. to the vane, and is 16ft. square. The church is lighted by a series of lancet windows 12ft. by 2ft. placed high above the floor level. At the south-east end of the building projects an organ chamber 12ft. square. Some relief is also given on the north side by the conical terminal to the circular stair, and also by the buttressed and embattled chimney stack which serves for the heating apparatus. In the basement at the east end an excellent parish room 25ft. square and 14ft. in height is obtained. The building is erected of local wallstone known as "insides," many of them strongly coloured with iron marks, and the dressings are of local sandstone. The whole is covered by Westmoreland green slate, with Staffordshire red tile ridges, overhanging eaves, and stone tabling. The body of the church is 84ft. by 25ft., and is 54ft. to the ridge of the roof, which is boarded, stained, and varnished. The interior is divided into seven bays, two of which form the chancel, and five the nave. The whole of the interior is lined with clean-cut wallstone, and the windows are glazed with cathedral glass, blotched with squares of stronger tints. The pulpit, choir seats, and low chancel screen, are of pitch-pine, the nave seats being temporary benches. The altar stands upon an oak pace, worked in chevron pattern, and is raised five steps above the nave. The font is of Caen stone, elevated upon a pediment of similar material. The church has accommodation for 300, and the building has cost £2,800, exclusive of site. The following are the contractors:—Masons, Messrs. J. Wilkinson and Son; joiner, F. Gawthorpe; plumbers, Haigh and Slater; slater, T. S. Stoner; painters, Cockroft Bros.; carver, Wm. Ashton; tiled work and font, F. Stako; heating apparatus, E. Thornton.

BEDSTONE.—The church of St. Mary, Bedstone, Salop, has recently undergone restoration at an expenditure of about £1,200. The church is one of the smallest, if not the smallest, in the diocese. It consists of a nave 32ft. 6in. long by 17ft. wide, and a chancel 16ft. 9in. by 13ft. 3in., and a small bellry. It is a plain structure of Norman, if not of pre-Norman date, and was last repaired about the year 1854. The architect, Mr. Kempson, of Hereford, in dealing with the church in the work of restoration, has carried out the stonework in work of Norman character. Four circular-headed lancet windows have been introduced in the south-west side of the nave. A single lancet window has been placed in the south side of the chancel, and another in the west end of the nave. The new bell turret is framed in oak, and placed over the west end of the nave, and measures 10ft. square; its base is covered with lead, and the turret itself is surmounted by a spire which is covered with oak shingles. The roofs of the nave and chancel are quite new, and are framed in a substantial and simple manner, and are covered with Broseley tiles. The floor of the chancel and the passage in the nave are laid with Godwin's tiles. Mr. Henry Welsh, of Hereford, was the contractor.

BRISTOL.—On Saturday last the new grammar school at Bristol was opened. The building has been designed by Messrs. Foster and Wood. The style is that of the 14th century. The dimensions of the ground line are 158 feet by 68 feet, and the height to the terminals of the gables is 90 feet. The east and west fronts are similar in character; one faces Queen's-road, and the other on the Tyndall's Park side, opposite the new road which will probably be some day made from the upper part of the park into Park-row. The building is of red local stone, with freestone dressings. The large schoolroom is 140 feet long, 50 feet broad clear of the walls, and 50 feet high from the floor to the collar-beam of the roof. The seats and desks provide accommodation for between 400 and 500 boys. The exterior lines of frontage are broken up by massive buttresses forming bays of each set of

windows. These buttresses terminate at a line marked with moulded cornice of freestone carried round the entire building, with gargoyles above the terminal of each buttress. The walls all round the structure are battlemented. The pointed roof is covered with green slate, and surmounted with terra-cotta cresting, a striking feature of the exterior wall being the turrets which rise above each transept. The turret on the west side contains the staircase leading to the clock-tower, and a private staircase by which the head master can reach the large room. The clock-tower has a cupola of copper of elaborate design, executed by Messrs. Chew and Sons, of Stroud. There are five bells connected with it, the heaviest weighing 9wt. The clock has been supplied by Messrs. Gillett and Bland, of Croydon. Cloisters at the north and south ends lead, on the north from the science classroom to the laboratory, and on the south to offices and lavatories, these adjuncts forming wings. The master's house stands in a prominent position on the high ground. The total cost of the building, including the site, will be nearly £20,000. The clerk of the works is Mr. George Salmon; the general contractors, Messrs. Wilkins and Sons. Mr. John Wilkins has done the plumbing and gas-fitting, and the gaseliers and pendants were supplied by Hardman, of Birmingham.

INCORPORATED CHURCH BUILDING SOCIETY.—The Incorporated Society for Promoting the Enlargement, Building, and Repairing of Churches and Chapels held its monthly meeting last week. Grants of money were made in aid of the following objects, viz:—Building new churches at Bromley, St. John, Kent, £100, and Camden Town, St. Michael, London, £450; enlarging or otherwise improving the accommodation in the churches at Castleorton, St. Gregory, near Tewkesbury, £50; Locklow, St. Bartholomew, near Leominster, £40; Harbledown, St. Michael, near Canterbury, £50; Marsh Gibbon, near Bicester, £20; Westleigh, St. Peter, near Bideford, £30; West Tilbury, Essex, £20; and Bettws-Guerfil-Goch, near Corwen, £30. Grants were also made from the Special Mission Buildings Fund towards building mission churches at Malin Bridge, in the parish of Wadley, near Sheffield, £10; Plymouth, Henry-street, All Saints', £25; and Springfield, in the parish of St. Mary's, Wolverhampton, £25.

CHIPS.

The Bristol Docks Committee on Monday recommended the Town Council of that city to purchase Avonmouth Dock at a cost of £600,000.

The Lambeth Guardians have appointed Mr. Scott surveyor of works for the reconstruction of the industrial schools at Norwood, about to be carried out from the designs of Messrs. Coe and Robinson.

From correspondence in the Cambridge newspapers, we learn that the authorities of Jesus College have repurchased in London all the carved woodwork of Bishop Aleock's time, formerly belonging to the college chapel, which was recently offered for sale by the rector and churchwardens of Landbeach.

On Saturday week a labourer named Thomas Whitwell was killed while at work in Pelrocktown Church, Devon, now in course of restoration, by the fall of a beam of oak which was being fixed in the roof.

The Watford Local Board of Health have just commenced the construction of a new reservoir at some little distance from the town. It is estimated to cost, with new main and cottage, £7,483.

It is stated that Mr. de Keyser has accepted a tender of £80,000 for the completion of his hotel at the corner of the Thames Embankment, opposite Blackfriars Bridge.

Amongst those upon whom the University of Cambridge propose to confer, on the 29th inst., the honorary degree of Doctor of Law, are Sir F. Leighton, P.R.A.; Mr. H. C. Sorby, President of the Geological Society; Mr. E. A. Bond, Principal Librarian of the British Museum; and Mr. C. T. Newton, of the British Museum.

The school erected to the memory of the late Rev. H. C. Hicks, at Hucknall Torkard, was opened on Monday. It is built in the Gothic style, of rough stone, with wooden casements and plain open roof. The schoolroom is 56ft. by 21ft., capable of sub-division into three by folding doors. Mr. F. Gratton, of Hucknall Torkard, was the architect; and Messrs. Holesworth and Green were the builders.

More than Fifty Thousand Replies and letters on subjects of Universal Interest have appeared during the last ten years in the *ENGLISH MECHANIC AND WORLD OF SCIENCE*, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Two-pence, of all booksellers and news-vendors. Post free 2½d. Office: 31, Tavistock street, Covent-garden W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 3fr. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—T. M.—W. H. B. and Co.—B. B. and T. Co. B. S. and H.—L. W. and Co.—C. H. and Co.—W. M. F.—S. E. Co.

OUR COMMONPLACE COLUMN.

C. F. W., G. H., C. A.—Notes or quotations on any subject of value in letter H will be received on and after the 27th inst. We wish to impress upon our contributors that the articles should be concisely written, and that data respecting buildings and materials are of greater value to us than definitions. We hope to publish another column next week.

Correspondence.

TEMPORARY BUILDINGS.

To the Editor of the BUILDING NEWS.

SIR,—In your recent article (p. 500), is the following:—"The erection of structures of a temporary kind at once light cheap, and portable is a want that has been strangely neglected by the architect, notwithstanding the numerous demands for such a class of structure and our colonising propensities." I feel that I am not one of those to be included in this accusation of strange neglect, and I trust that the following short description will prove this, and give some idea of what I have been doing in this direction and the improvements I have effected. I have arranged, I believe, an entirely novel system of portable buildings, either in wood or iron; temporary, or rendered so complete that they will meet all the requirements of a permanent abode.

In forming the panels or walls of wooden buildings it has been usual to use wood quartering or framing, and to fix upon it weather boarding externally, and matched tongued and beaded boarding internally. The nature of the weather boarding to spring away from the quarters to which it is nailed, by the action of the weather, necessitates the quarters being closer together than is required for constructive purposes, and adds to their weight in carriage and unwieldiness in handling.

By my system, I dispense with all quartering, and form panels, say, 8ft. high, corresponding to the height of an apartment or story, and 4ft. wide for convenience, having weather boards externally laid, horizontally grooved on the edges, and fixed so that the edges interlock the side of one groove entering as a tongue into the hollow of the other. The internal face is of tongued matched and beaded boarding laid vertically. Between the inner and outer boarding there is a sheeting of inodorous felt, and the two thicknesses of boarding are nailed and clenched together, forming a perfectly rigid panel free from all liability to rack, and weather-proof. The inside boarding

is wider than the outside boarding, so as to extend beyond it, forming a projection or tongue on each edge, which fit into corresponding vertical grooves on the standards set up when the building is erected at the required distance apart to receive them, and in these grooves the panels are retained without any further means of attachment. The ends of the weather boards butt up against the solid portion of the standards, thus forming a rebated weather-proof joint, and avoiding the labour of shaping the grooves to the ends of the standards.

The standards and other constructive parts to receive the panels consist of angle posts grooved two sides to receive the external panels; intermediate grooved two sides for joining the panels; junctions, grooved two sides for the panels, and inside to receive partitions; door-posts grooved one side for panels and the other side rebated for the door; casement frames, &c., the like. Also transomate gables; caps, sills, &c., which are grooved to receive the horizontal edges of the panels.

The internal partitions are of the thickness of matched tongued and beaded boarding, one laid vertical, the other perpendicular, with a sheeting of inodorous felt between. All the standards, &c., are fixed to the sills, plinths, &c., with gas-barrel dowells.

The roof is formed of panels having quarters covered externally by preference with galvanised corrugated iron or zinc, and the soffit with matched tongued and beaded boarding; the cap to receive the wall panels being fixed to the soffit. There are no constructive timbers except the ridge. I have built permanent brick houses and bungalows here with roofs of more than 40ft. span, without any framings or other timbers, only the common rafters and the ridge.

In your article, galvanised corrugated iron is thus described:—"Anything more tasteless, comfortless, and forbidding than the corrugated iron church of the usual type is scarcely possible to find." I fully endorse these remarks, and consider that hitherto this material has only been applicable to buildings of a certain class and use, by reason of the difficulty of forming the angles and joinings, and fitting and fixing the doors, windows, and other parts to the openings. And when these have been done, the general effect of the exterior is scarcely to be tolerated.

By the application of the system I have described to wooden erections, and with the following modifications, this material becomes equally applicable for the exterior of buildings, and the manner in which the corrugations are broken up into panels by the stiles which are of wood presents a good appearance, and the corrugations give a pleasing indentation on the panel, more particularly when the material is painted.

The panels for the outside walls are formed of sheets of iron, their length by preference corresponding to the height of the apartment or panel to be formed, and their number being sufficient to form the width of the panel, which is by preference two sheets, that is 4ft. wide. At the vertical edges of the panel, and at the vertical joinings of the plates, small quarters of wood are placed from end to end of the panel. The quarters on the side which is to be against the iron are shaped so as to fit the corrugations, and those at the vertical edges of the panel are flattened so as to enter the grooves on the standards. Cross pieces are attached at suitable distances apart. This framing is overlaid with a sheeting of inodorous felt, and over this matched tongued and beaded boarding is laid horizontally, and nailed to the quarters, the ends being flush with the quarters at the vertical edges of the panel. The lower edge of the bottom board will rest upon the floor. To this framing the iron is secured by screws to the quarters. Thus a portable and completely finished panel is formed ready for fixing to the standards and other parts described to the wooden building.

A weathering or front over door and window openings is formed by strips of zinc or lead fitted at the lower edge of the corrugated iron opening. The upper part is corrugated to fit beneath the corrugations of the panel to a height or lap sufficient to keep out the rain. The lower part of this strip, where it is not beneath the corrugated iron, is not corrugated.

I hope at some future occasion to describe the buildings that have been erected, or are now in course of erection, ranging from a bungalow of 16 rooms to one of only two, also billiard-rooms, &c., and how it is now being worked out so as to supply what appears to be one of the wants of

the present day, viz., portable buildings prepared in panels readily fitted and light for railway or other carriage, easily set up in the required place, economical in price, easily removed or enlarged by the introduction of panels, which are all interchangeable, and if the building is wished to remain that it will answer all the requirements that are looked for in a permanent abode or for other purposes.—I am, Sir, &c.,
Westcliff, Birchington. JOHN TAYLOR.

THE ARCHITECTURAL REJECTED AT THE R.A.

SIR.—A friend of mine, a graduate, writing from one of our universities on the above subject the other day, makes the rather drastic assertion that "the Hanging Committee at Burlington House ought themselves to be hanged," and notwithstanding its having been quoted as an old saying originally said by an exceedingly eminent painter, I am ready to admit that the statement "savours rather of the gutter." It can never do any good to throw dirt, and I have no desire to impute motives to the Hanging Committee of the Royal Academy. As far as paintings go, the R.A. seems to treat rising young men very fairly as a rule, though some of the members perhaps take too much advantage of their position in hanging their own pictures. It is not, however, in the department of painting that I would turn for a moment, but to Gallery No. IX., where the architectural drawings of the year are hung. And while here I would determine, if possible, upon what system of selection the assortment is made. I have often tried to do this before, and no doubt shall do so again, but thus far no other term can I find to describe that system than this, "the inexplicable." Perhaps someone may be able to enlighten me, and I am only one of the numerous class who at present echo the term "inexplicable." My experience extends (with regret be it said) over a rather long series of Royal Academy Exhibitions, and I am one of the few who have had the advantage of examining the collection of rejected architectural drawings standing below in alphabetical order in the vaults at Burlington House, waiting the "regrets of the Council" to be sent out to the authors announcing their fate. Here in these vaults I have seen very many old friends in the way of drawings, several who had been there before, and some whom I have seen since enjoying the full glory of the public gaze on the walls of Gallery No. IX. Indeed, it is by no means a rule that if a drawing be rejected one year that it will not be hung the next. In the present Exhibition there are drawings which have gone through this ordeal, doubtless on the principle that some things improve by keeping. Of course the Royal Academy cannot hang everything, neither can they please everybody, and I know perfectly well what a tedious and unenviable task it must be to wade through the mass of material submitted for exhibition. I am assured by one of the members of the Hanging Committee that the utmost care is taken with every several selection, and that each subject is individually voted upon, and further, it is said that the Council become more and more particular every year. Quite right, everyone must say, never was there more need for such a strict *regime*. But still I cannot rid myself of the thought "Inexplicable," so great is the contrast between theory and practice, and I turn to the few architects' works represented by the accepted pictures now on the two walls, and a bit of Gallery No. IX. for an explanation. There I certainly see some undoubtedly good work, and more unquestionably bad, judge them by as lax a code as you will. This is an old, a very old experience, and so is the allotment of such very little space, out of the entire series of sixteen galleries, for the exhibition of architecture, as can readily be seen by reference to those who have written in the professional journals ever since there were such things, and all the technical papers this year have re-echoed the complaint. But what cares the R.A.? The members are in power, and they will tell you that they have done their best in making the choice now set forth from Nos. 1,068 to 1,163. These numbers not only represent good works and bad, but well-known names and unknown. The works of people one has never heard of before sometimes get well hung, and for this principle I have nothing but praise. That is how it should be; but then these strangers more than often figure on the walls

with the most commonplace and unsuitable subjects. Thus the selection remains inexplicable, seeing that it is not made upon the principle of choosing only the very best drawings of the year, or representative architecture of the year, neither is it made by selecting only the works of well-known men. And so from the accepted I turn to a few names and works of the rejected drawings with a hope of finding an explanation. Remembering that Sir Gilbert Scott once had a large drawing of the Midland Hotel at St. Paneras, coloured by Mr. H. W. Brewer, rejected, one need not be surprised to find the following company of names among those who had works rejected this year, and I will venture so far as to mark with an asterisk those names whose drawings in my opinion should have certainly had a place in preference, at any rate, to some in the show. Perry and Reed; G. Corson; D. Brandon; Adolphus Cane; J. Cole; Fergusson; E. E. White; E. C. Lee*; Aston Webb*; A. Peebles*; J. James; Henman and Harrison; Jones; Batterbury and Huxley; Ernest George and Peto; W. Niven; W. Millican; Talbot Brown; W. Fawcett*; H. Gribble*; J. Brooks, Theo. Allen; J. M. Brydon; T. E. Colcutt*; J. O. Scott*; T. H. Wyatt; R. Plunbe; M. B. Adams*; Leeming Bros.; Lansdowne and Harris; J. P. Seddon*, J. and J. Belcher; J. Medland; O. Hansard; H. Gundry*, E. J. Micklethwaite; E. J. Tarver; St. Weatherly*; H. W. Lonsdale*; Swinden Barber*; P. J. Marvin; J. Hicks; Basil Champneys*; Ralph Nevill; W. F. Lyon; and others. But these are enough simply as representative of the rejected, while among those who nearly escaped such company was Mr. G. G. Scott, who received the refusal card for all the pictures which he sent, but these now represent him at the R.A. His first intimation that they were really hung was simply the fact of his seeing them on the walls on the opening day. For myself, I have had as many drawings hung at Burlington House as most people, but I cannot but feel that some of my best have been among the refused, and so whether I turn to the accepted or the rejected, or to my own experience, I find no other interpretation of the method adopted at Burlington House for the hanging of the architectural subjects than that of a sort of pot-luck frame-fitting system, and surely this is quite unworthy of such an illustrious institution, even though it feels obliged to relegate so finite a space to what its leading architectural member tells us is the "Mother of the Fine Arts—Architecture."—I am, &c.,
BOTH ACCEPTED AND REJECTED.
May 17, 1879.

CREOSOTED TIMBER.

SIR,—I am glad to see, by the correspondence in your paper, that the evidence given by Mr. Robert Walker at an inquest lately has had the effect of bringing out remarks which are likely to do away with some of the absurd and ridiculous notions now in vogue about creosoting. My first experience in the Bethell's Process was as inspector under the late Sir I. K. Brunel, and till now, over thirty years, I have been constantly engaged in the different processes for preserving timber; from this your readers will perceive that I have some qualification to speak on the subject. Timber very seldom needs that the creosote should penetrate to the heart of the wood; those who have seen the exhibits of creosoted timber at the last Paris and other exhibitions will have noticed pieces of sleepers, telegraph poles, and marine timber, which have been in the ground or water from fifteen to twenty-five years, the hearts of which are scarcely a shade darker than the day they were cut. It is obvious that if timber is to be creosoted to the heart the oil used would be far greater than the usual quantity injected and found to have such universally good effects. Of course the ends of the timber will be black right through, as this is where the creosote enters, and this fact totally falsifies Mr. Walker's idea that the inner pores exert any capillary action on the water, the ends of the timber being thoroughly and hermetically sealed against all moisture. It is very important that all cuts in submerged timber should be done *before* creosoting; unless this is done, as the inventor and patentee said many years ago, the process is deprived of much of its usefulness, as the waterproof coating formed by the creosote is penetrated. Inspection also is a point on which too much stress cannot be laid, to see that the timber is in a proper state and sound for the process, and that the specified quantity of oil is injected, and the inspector's

authority should be respected. I could lay my hands now on timber which has been so-called creosoted in spite of the inspector's opinion that it was too wet. It was wanted immediately, and what wonder that it decays or is eaten by marine worms far sooner than *properly* creosoted wood? Proofs of the efficacy of the process are needless to any engineer of experience; I have collected many during past years, and shall be most happy to show them and give every information I can on the subject to those interested. Being absent on the Continent must be my apology for not replying before.—Yours obediently,
WM. JAS. BRAIN.

ASPHALTE AND TIMBER FLOORS.

SIR,—In your impression of April 25, p. 460, you refer to a new method adopted in France of laying oak flooring, namely, that of embedding the battens in a layer of hot asphalt, instead of nailing them in the usual manner upon the joists. The system, may I be allowed to state, far from being a novel one, has been practised with great success for a number of years, and has obtained a wide application in Hungary and Germany.

The section adopted is as here shown, solid lin.

thick, size about 20in. by 4in. or more. Similar material I can supply ready for laying at 9d. per foot super., or £3 15s. per square. The laying may be accomplished by any skilled joiner.

J. T. E.

HEATING APPARATUS.

SIR,—I see in your Notes from Edinburgh last week, you say that the heating apparatus is not always successful. Why can it not be? With arrangements for the warming of air as now prevails in the majority of churches, I grant you that it is so, except you use the cast iron arrangement and burn the air to ribbons, but it is not difficult to pass volumes of pure warm air into churches at all, in the very coldest weather.

I have been struck with the report of The Hertford British Hospital, in Paris. You therein say "The ventilation is well provided for"—but, you do not say how it is accomplished. Then you say that the building is warmed by means of warm water pipes, laid in floors and covered with iron gratings. What arrangement is there to prevent the germinating of zymotic diseases in these little dens most favourable for their development? The more I read the more I am puzzled. This great hospital, the latest production, seems to be the very place for the germinating of the diseases the whole nation has been writing and talking about annihilating. It may be that I am quite wrong, so I write to be corrected—this is my apology.—I am, &c.,
G. S.

A new Baptist chapel was opened last week at Walsall. The style is Italian, the materials used externally being red brick, with dressings of Hollington stone, enriched throughout with moulded and carved caps, arches, and cornices; and the roof is covered with Bangor slates. Internally, the chapel is 62ft. by 44ft., exclusive of the orchestra, and 30ft. high from the floor to the ceiling. It is fitted with galleries on three sides, and provides 680 sittings, exclusive of the orchestra. In the rear is a lecture hall, 30ft. by 16ft. Mr. W. F. Markwick, Walsall, is the architect; the builders are Messrs. Rowley, jun., and Synex. The cost is £3,368.

The eastern portion of Holyrood Palace has just been re-roofed, for the first time since it was built, at a cost of about £1,000. The part of the Palace which has been operated upon is immediately above the Queen's apartments, and it is expected that, in the course of next year, the roof of the south wing, containing the apartments occupied by the Lord High Commissioner and suite, will be similarly dealt with. The work just completed has been carried through under the superintendence of Mr. Robertson, of H.M. Board of Works.

Our description last week of the new Derby Free Library, on p. 552, furnished from a local source, turns out to be inaccurate in one or two particulars, which the architect has kindly corrected. The builders are Messrs. Woods, of Blackburn and Derby; the architect is Mr. R. K. Freeman, of Bolton; the style is Jacobean, and the cost (stated at £15,000) will include additional buildings yet to be erected. The first contract was let for £7,600, being within £100 of the architect's approximate estimate.

Intercommunication.

QUESTIONS.

[5770.]-**Perspective.**—I should be obliged if any reader would recommend a thoroughly good work on perspective, especially containing directions for treating interiors.—L. MASON.

[5771.]-**Government Appointments Abroad.**—Can any reader tell me if there are any appointments as architects or land surveyors (under Government) abroad? If there is any examination to pass to procure same, and where could I write for full particulars?—S. C. G.

[5772.]-**Red and White Wood.**—Would any fellow-reader kindly give me a ready and sure rule to distinguish between red wood and white wood? I have had some timber used lately, which the contractor assures me is of the former class, yet it is the very palest in colour.—KIFFAX.

[5773.]-**Lime.**—Perhaps one of the correspondents of the BUILDING NEWS would kindly explain what "fat" lime is, also the difference between it and "roach" and "quick"? The three terms one often meets with, and they puzzle—AN IGNORANT MAN.

[5774.]-**Thrust of Arches.**—A row of 8 shops, with a frontage of 20ft. each, with brick fronts and two windows on each floor and three floors in height, is built on piers 18ft. by 24ft. and 12ft. high, the arch 18ft. by 18ft., with 1ft. rise and 18ft. span between piers; will some reader kindly explain how the thrust of the arches is calculated, as I think it must be greatest at the ends, and as the ends are corners and required for fronts for shops, how would be the safest way to carry the weight above, as it would not do to put an arch at the end without any abutment except a pier, and to put a breastsummer would be almost as bad, as I think the thrust of the arches would force the corner out of upright? I shall be glad of any information on the above, and an example worked out in plain figures from the description I have given, and allowing the weight of walls and floors as 50 tons weight on each arch, and also on each corner shop. And what would be the formula for safe load for brick piers of the size above, 18 by 24 of stock bricks? An early answer would oblige.—ONE IN A FIX.

[5775.]-**Heating Kiln.**—Please insert following query. We have had it inserted in several papers but have got no answers, so we send it to your journal to which we have been subscribers for many years. Will some of your readers give us the best and cheapest mode of heating a shed 20ft. wide, round a Hoffman kiln, as per inclosed sketch. 1. Large drying shed round the kiln. 2.

Flues from boiler. 3. Stack. 4. Marine boiler. 5. Tube boiler. 6. Two engines for driving machinery. 7. Smoking chambers. 8. Brick burning chambers. Diameter of kiln 8ft. Brick pillar under each principal and closed up, with wooden doors all round. 1. Roof. 2. Top of kiln. 3. Drying shed. 4. Flue. 5. Brick burning chamber. 6. Smoking chamber. 7. Stack.—WOODWARD AND CO.

[5776.]-**Stamping External Plaster.**—Can any reader give me a description of the method of stamping external plaster work and where the dies for same can be obtained.—AJAX.

[5777.]-**Drawing Ink.**—Where can the drawing ink, made by Mr. Featherstone, of Chertsey, referred to

by Mr. Neale in his late paper, be obtained, or how is it made?—T. DREW.

[5778.]-**Latham's Water Supply.**—Would any correspondent kindly say if Mr. Baldwin Latham's long promised work on "Water Supply" has been published, and if so by whom?—W. M. M.

REPLIES.

[5723.]-**Coloured Building Stones.**—I should like to say a few more words in reply to your correspondents, some of whom seem to ignore all colours in stone except that of red. I therefore reply in respect to that colour only. I understand the question as first propounded to refer to a variety of colours, hence my reply. I beg to inform "J. W." and "G. F." that the whole of the red stone in the Hand in Hand Insurance Offices is Corsehill stone, supplied from the Corsehill quarries on the Solway Frith, near Annan, N. B. Corsehill stone is sometimes called Dumfries, but this is a mistake. Corsehill is much denser stone and a better weather stone than the red stone supplied from the quarries round and about the town of Dumfries. Moreover, the beautiful carving in the "Hand in Hand" could not have been done in the soft, friable, red stone. The cantilevers of the red brick mansions near Gloucester-road station (now covered with pigment) are of a red stone, from which the colour has faded. The light coloured red columns in the south facade of the Law Courts are made out of stone which does not retain its original red colour. The dark red stone in the Gloucester-road bridge is Corsehill, supplied from the Annan Quarries. The light-coloured stone in the same bridge is from the Mansfield Quarries. The difference in colour will become more marked as time rolls on. I fully agree with Mr. Saville in his remarks upon the light and dark coloured red stones at the St. Pancras Hotel. Undoubtedly, as he says, light-coloured red Mansfield (although its colour fades) is a better stone than the darker coloured Mansfield. Some of the latter was used for the bases of the lamp-posts in Southwark-street, which are now decaying. Some of the dark red stone in the terraces and coping at St. Pancras station is Corsehill, but this building is not a good example of the use of red stone, as it (the red stone) was supplied from several quarries.—SAMUEL TRICKETT.

[5753.]-**Abutments.**—In reply to "W. J. P." I have carefully examined my paper on abutments and find what "W. J. P." says is correct. I was, when I wrote it, deficient in spare time and disposition to write same, but did not like to let question pass unanswered, and I thank him for his reply.—HENRY ANSOE.

[5745.]-**Wood Roofs.**—ERRATA.—In last week's reply, 60th line, read "increases inversely," &c. 2nd column, 6th line, for "now of length in feet, squared," take out the comma and let it read as follows:—"Now of length in feet squared and multiplied by the integral number of which W was composed." 2nd column, 18th line, for " $2 = \frac{1 \times 1 \times 2}{2} = 1$," read "whence our 2 which has now become 1 by dividing both sides by 2 we have $1 = \frac{1 \times 1 \times 2}{2} = 1$." 27th line, read "because if the constant 20," 29th line, put 25 for 20. 36th line, read "but not necessarily so small in smaller ones."—H. A.

[5750.]-**Timber Verandah.**—"G. H. G.'s" reply is totally without foundation. It is a well-known fact that oak subjected to alternative wet and drip, as in the case of porch or verandah will stand the weather better than any other wood. "G. H. G." would do well to study the nature of the different woods before giving his opinion in such an absurd manner. Oak can, of course be treated in the same manner as all other woods to suit the taste of "W. W. W."—AXIUM.

[5766.]-**Purification of Sewage.**—Write for the "Suggestions as to the Preparation of District Maps and of Plans for Main Sewerage and Drainage and Water Supply," published by George E. Eyre and William Spottiswoode. If you have fall sufficient, I advise you to put your sewage on land and leave alone all other makeshifts such as settling tanks, filtering tanks, &c., &c.—WM. JACKSON.

STAINED GLASS.

GREAT BEDWYN.—A stained-glass window has recently been placed in Great Bedwyn Church, Wilts, by the Marquis of Ailesbury, in memory of his parents. The subject introduced is "The Ascension." The work has been carried out by Messrs. Heaton, Butler, and Bayne, of Garrick-street, London.

WATER SUPPLY AND SANITARY MATTERS.

COCKINGTON, DEVON.—The Torquay water supply has been extended to the parish of Cockington, and the newly constructed reservoir above the latter village was formally filled last week. The reservoir stands at an elevation of 280ft. above the sea, and is supplied from the Torquay water main, which brings the water from Tottiford-on-Dartmoor, about 15 miles distant. The capacity of the reservoir is 50,000 gallons. The work, which was done by Mr. Shaddock, of Saltash, has been carried out in blue lias masonry, lined with Portland cement. The additional water-pipes have been laid by Messrs. Sanders and Sons, contractors, of Torquay. The plans and specifications were prepared by Mr. Weeks, the Torquay Waterworks superintendent.

A new workhouse chapel is about to be built for the Epsom guardians. Messrs. Furniss are the builders.

LEGAL INTELLIGENCE.

THE FITZALAN CHAPEL IN ARUNDEL CHURCH.—Duke of Norfolk v. Arbutnot.—Judgment in this case was given in the Common Pleas Division on Saturday last. The action, it will be remembered, was tried during the last sittings, by consent of the parties, before Lord Chief Justice Coleridge, sitting without a jury. The action in form was one of trespass against the Rev. George Arbutnot, vicar of Arundel, for breaking down a wall which had been built by the duke to divide a part of the church, known as the Fitzalan Chapel, from the rest of the church. The duke claimed the absolute property in this chapel, which was built on his land, and prayed for an injunction to restrain the defendant from further trespass. The vicar, on the other hand, by his statement of defence, set up a claim to the chapel as being a part of the chancel of the church, and prayed for an injunction against the duke to restrain him from obstructing the right of the parish to light and air by building the wall in question. The case occupied four days, and raised many questions of interest to other than legal minds. The Fitzalan Chapel had for centuries been the burial-place of the Howard family, and evidence was given at the trial of an exclusive use of it by the duke's ancestors, stretching over 400 years. The chapel was separated from the body of the church by an iron grille, coeval with the church itself, the key of which was proved to have been always in the custody of the duke or his servants, and it was shown that visitors had never been permitted to visit the chapel except by permission of the dukes. Great stress, too, was laid, on behalf of the duke, in the circumstance that, though the chapel had been suffered to get into a grievous state of squalor and decay, no complaint or assertion of any right had been made by the vicars downward from the Reformation until the bringing of the present action; and moreover, that in the visitations of the Bishops of Chichester from 1762 to 1875 not a single bishop or archdeacon had made any claim to the chapel, and the churchwardens had invariably returned in their reports that the chancel was in good repair at a time when the Fitzalan Chapel was notoriously in the worst state possible of disrepair. The case for the defendant, on the other hand, rested chiefly on the architectural aspect of the chapel, from which it was sought to draw the inference that the building being proved to be an integral part of the church was either a part of the great chancel, or else a lesser chancel; and to strengthen this view of the case, Mr. Butterfield, the eminent architect, was called as a witness by the defendant. Mr. Butterfield had examined the church and chapel, and gave it as his opinion, from the appearance of the whole building, considered architecturally, and the position of the ancient pulpit and high altar in the interior, that there was nothing to suggest to his mind that the Fitzalan Chapel was anything else but part of the chancel of the church. A number of ancient documents, many of them in mediæval Latin, connected with the history of Arundel, formed the rest of the evidence in the case, and were relied on, with equal confidence on either side, to establish the particular views contended for. His Lordship said the principles on which his decision rested were simple and familiar, and if he had taken time to consider his judgment it was more out of regard to the interest attaching to the case than from its difficulty. He was prepared, before the trial commenced, to find that many questions of fact would be disputed, and with that impression he had paid a visit to Arundel Church and inspected the locality, the better to appreciate such points when they arose; but, in point of fact, the evidence produced had been all one way and in favour of the plaintiff's contention. The acts of ownership on the parts of the Dukes of Norfolk had been proved to be many and various. Numerous instances had been given of interment in the chapel without any faculty having been obtained for that purpose and without registry. Instances also had been furnished of the disinterment of bodies at the free will of the duke's ancestors. The chapel itself dated from the 14th century, and the grille or gateway which separated it from the rest of the edifice was fastened by a lock on the chapel side, the key of which had been always kept by the dukes or their stewards. Strangers had been excluded since the Reformation, and the way in which this beautiful building had been treated by the Dukes of Norfolk was in itself the strongest evidence of ownership. One hundred years ago there was a beautiful arched, carved roof, which had now disappeared, and the chapel contained ancient monuments of the Howard family, which had been suffered to fall into a state of dirt, neglect, and mutilation, which many families far less illustrious than the Howards would never have tolerated, and admission, which for three centuries was persistently denied to vicars and parishioners, had been freely granted to owls and bats. It was contended that no remonstrance had ever been made against this state of things, because the Dukes of Norfolk were powerful noblemen, and acquiescence was the best discretion under the cir-

circumstances: but it was to be remembered as against this, true as it was in one sense, that this long line of noblemen, who were Dukes of Norfolk and Earls of Arundel, had for centuries belonged to a religious belief which had been persecuted from the time of Elizabeth to the reign of George III. in a way that was disgraceful to a civilised country. It was impossible to think that if a belief in any right to the building had existed in those times it would not have been asserted either by the vicar of the parish or the bishop of the diocese. He had come to the conclusion, therefore, that the right of ownership in the Dukes of Norfolk to this building had been proved by the strongest possible evidence, and that the ancient documents which had been referred to in the argument in connection with the history of the church as tending to prove one collegiate church did not show so much that the College of Arundel had the building now claimed for their chapel as that they had certain rights in connection with the old parish church at the same time that the parishioners had other rights. With respect to the evidence which had been called for the defence, his Lordship said there was nothing to prove that services had ever been held in Fitzalan Chapel, or that the different Bishops of Chichester had ever exerted any authority over it. There were, indeed, Protestant burials from time to time of members of the Arundel family, but it may well have been that those who were so buried there were interred in accordance with their own expressed wish before their decease, or with the consent of their Roman Catholic successors after death. Then there were the returns by the churchwardens at the visitations of the bishops. What did they show? In answer to the questions as to the state of the chancel of the church the answers were "good," or "very good," or "excellent," and this at a time when the chapel was in a state of notorious squalor and decay. The answers with regard to the tables of the Ten Commandments were to the same effect, by reporting that they were at the east end of the chancel, when there were no such tables in the chapel. Mr. Butterfield's evidence as to the architectural features of the building was entitled to the greatest respect; but what Mr. Butterfield saw was obvious to an ordinary observer, and his evidence was but an intelligent exposition, on architectural grounds, of what was a patent fact. Granting, therefore, that the Fitzalan Chapel was an integral part of the whole fabric of the church, what did it show? The cases of "Chapman v. Jones" (L. R. 4, Ex. 273) and "Churton v. Frewen" (L. R. 2, Eq. 634) were authorities that an integral part of a sacred edifice could be vested in a private person, and a number of instances were to be found in Mr. Freeman's paper, which had been referred to, on ancient churches, where different parts of the building were vested in different owners. With respect to the defendant's claim for light and air, the defendant himself had built up a wooden partition where the present wall now stood, and had placed there a Communion table besides. The litigation had been conducted with courtesy on both sides, and it seemed to him that concessions might fairly be made with respect to light and air which would meet the views of both parties. He, however, had only to deal with the case as it came before him in law and in fact, and upon them he gave judgment for the plaintiff for 40s. and costs, and granted the injunction prayed for. He also gave judgment against the defendant in his counter-claim.

CHIPS.

A double-page perspective view of Mr. Alfred Waterhouse's new building in Holborn for the Prudential Assurance Company, photo-lithographed from a drawing by Mr. J. G. Buckle, will appear in the *Commercial World*, of June 2.

Plans prepared by Mr. J. Wm. Cockrill, architect, Gorleston, have been approved by the Education Department for additions to the Stradbroke-road Schools, Gorleston, for the Great Yarmouth School Board.

The Great Yarmouth Town Council, acting as the Burial Board for Gorleston and Southtown, have purchased subject to approval of Local Government Board, 9½ acres of land to be laid out as cemetery. The plans are being prepared for necessary buildings, &c., by Mr. J. Wm. Cockrill, architect, Gorleston.

A faculty has been granted for the repairing and restoration of Petworth Church, Sussex.

The tender of Messrs. Jeffrey and Son has been accepted for the required additions and alterations to the premises taken in New-street, Birmingham, for the Liberal Club. The architects are Messrs. Harris, Martin, and Harris.

A temporary church was opened at Moseley at the corner of Oxford and School roads on Thursday evening. It is of wood, plastered inside, with slate roof, and seats twenty-five persons. The builder was Mr. Collett, of Balsall Heath.

Our Office Table.

THE annual meeting of the Sunday Society, which advocates the opening of museums, art galleries, libraries, and gardens on Sundays, was held on Saturday afternoon, at the Freemasons' Tavern. Sir H. Thompson presided, and among those present were the Earl of Dunraven, Lord Dorchester, Viscount Powerscourt, Mr. J. C. Dundas, M.P., Sir Arthur Hobhouse, Admiral Maxse, the Rev. S. Hansard, and the Rev. H. R. Haweis. Resolutions were passed expressing satisfaction at the progress made, and at the result of the late division in the House of Lords, requesting members of mechanics' institutes, workmen's clubs, and trade societies to appoint delegates to represent them on the national council of the Sunday Society, and calling upon electors to give due prominence to the question at the coming general election.

The modest dwelling, No. 17, Eldon Place, built by the late Mr. Barnup, of the Barras Bridge, Newcastle-upon-Tyne, about the year 1815, and still in the possession of his family, has, by association, become a place of historical interest as the joint residence of two of its most illustrious townsmen, viz., George and Robert Stephenson (father and son), at the time when they were commencing those labours which have conferred such a boon, not only upon that town and nation, but upon the world. A few gentlemen have instructed Mr. Craggs to prepare and fix, in front of the above-named house, a tablet of Cornwall red serpentine marble, bearing the inscription: "The residence of George and Robert Stephenson, 1824-5." The former indicates the date of the commencement of the works in South-street, the latter that of the opening of the first of the local railways, the "Stockton and Darlington."

On July 20th an International Art Exhibition will be inaugurated at Munich, and will remain open until the end of October. It will be held in a building specially erected for the purpose, and wholly constructed of iron and glass according to the plans of a local architect, formed after consultation with a committee of leading artists. One special feature is that the vestibule and the other larger rooms are to be decorated by the chief painters and sculptors of Munich, and in doing this all will work according to a harmonious design, and with the object of concealing the greatness of the wall space. The adornment of the vestibule is to be almost entirely of an architectural character, but so as to prepare the visitor for what he will see in the rest of the building. In order to lighten, as far as possible, in the case of foreign artists, the trouble of sending their contributions and of taking care of them when lodged in the exhibition, as also with a view to protecting their interests generally, it has been decided that foreign artists may exhibit "collectively," either as a nation, or in any other united capacity. This improvement on the original programme, which contemplated that all contributors should exhibit individually, is due especially to representations from Austrian and French artists, who it is reported, purpose sending large and valuable contributions to Munich.

THERE are now at least three projects for great maritime canals before the world. The nearest is the canal in continuation of the Garonne to the Mediterranean, which would render the Straits of Gibraltar obsolete in the passage from England to India, and save two or three days which are now occupied in passing round Spain. The next is the cutting of the Isthmus of Corinth, which would place Athens on the sea way from Trieste to Constantinople and greatly abridge the passage between those parts. The most distant—the proposed canal across the Isthmus of Panama—is the most formidable undertaking of the three.

AN amusing instance of an engineer being hoist with his own petard occurred at Falmouth last week. A town councillor named Thomas has complained bitterly at the council meetings of the defective drainage on the premises of a neighbour, and at the last meeting gave notice that he would move the dismissal of the borough surveyor for neglecting the sanitary interests of the town. The council thereupon passed a resolution instructing the surveyor to visit the block of buildings complained of. This was done on Thursday, and on the surveyor,

medical officer of health, and police superintendent going into Mr. Thomas's own premises they found in his cellar four tons of diseased meat, decayed cheese, and other matters, which by the orders of the medical officer were at once removed in carts to a field outside the town, and the magistrates and sanitary committee were summoned to view the collection. The magistrate at once gave orders for the whole to be destroyed and buried in quicklime in some place removed from any dwelling. This was done on the following day at the expense of the too sensitive town councillor.

A NEW railway is being made across Dartmoor for the West of England Peat Company, from the South-Western Company's station at Bridestowe to the peat beds at Rattlebrook; and last week the directors of the new railway company visited the line, which is now about half-finished. The railway is of the same gauge as the South-Western, with similar permanent way, metal, and fastenings. The total length is 4½ miles, and at its highest point—at Amicombe-hill—it rises 1,015ft. above the level of Bridestowe Station, and 1,803ft. above sea-level, being the highest point yet reached by a railway in England. The gradients range from 1 in 28 to 1 in 42. There are only two bridges. The total cost will be but £10,800; Mr. Howard is the engineer; and Messrs. Brotheridge, of London, are the contractors. It is in contemplation to use the line, when finished, during the summer months for passenger traffic, and eventually to extend it through Walkham Valley to Princetown, about seven miles from the present terminus.

A NEW hunting-ground for beating up competitors for the designing of new buildings was suggested to the Battersea vestry last week by a Mr. Gerrard. That gentleman proposed that with a view to facilitate the erection of a vestry hall suitable to the parish, and to encourage schools of design, invitations should be addressed to the schools at Lambeth, Chelsea, Kensington, and any others the Vestry might think fit, offering £50 to be divided between the three best designs. This magnificent premium was to be divided into three sums of £25, £15, and £10, in order of merit of the designs, but as the Vestry have not decided upon a site, the ingenious proposal for getting cheap designs from lads utterly untrammelled by architectural canons, fell to the ground.

WITH regard to the defects in the new town-hall at Ipswich, revealed at the last meeting of the Town Council, and to which we referred last week (p. 556), an Ipswich stone-mason, Mr. H. Jackson, has written suggesting that the state of things then disclosed should be laid at the door of the Building Committee of the Council and the architect, rather than the builder, who has nothing to do with the selection of the materials to be used. In conclusion, he makes the following suggestions:—"By no means pull down the balustrade and cornice and refix it, as was suggested in the report piecemeal, as I am sure it cannot be fixed so well again; secondly, cut out all the defective work entirely, and replace it with Portland stone, which can be done without taking the upper cornice down; thirdly, take out every cantilever one at a time, and replace them with good Portland stone, and well point up all joints with Portland cement; fourthly, the work to be well dried, then coated with linseed oil. I consider the solution of silica to be totally unsuitable for the purpose, for it has been tried in Ipswich, as well as on the Houses of Parliament in London, and has proved to be a failure; fifthly, it is very important that the Council should appoint some practical and disinterested stone-mason from a distance to superintend the work."

THE largest bridge in Europe will be completed next year. It will cross the Volga in the Government of Samara, Russia, on the Siberian railroad line. The Volga, at the point of the bridge, is about four miles wide in the spring season, and in the autumn is 4,732ft. The bridge will be supported by 12 piers 85ft. high, with ice-cutters 35ft. high, at a distance of every 36ft. The ice-cutters are covered with granite. The iron work is from Belgium. A temporary colony is established for working-men employed on the bridge. It occupies about 55 acres, and has 60 different buildings, insured at 100,000 roubles. Two thousand men are employed, and among them are 100 Italian masons. Three steamers and 70 barks are used constantly for forwarding wood, stone, iron and other materials. The bridge will cost 4,630,000 roubles, or about £700,000.

THE Hampstead Hospital case having concluded yesterday, the Lord Chief Justice, after consultation with the other judges, delivered judgment. He said the Court were of opinion that the rule for a new trial should be made absolute. The jury had been called upon to decide two main questions; firstly, whether the hospital was such a nuisance as to give the plaintiffs (Sir Rowland Hill and others) the right of action; and, secondly, whether supposing the defendants, the Asylums Board, were protected by Act of Parliament, they had conducted the hospital in so negligent a manner as to render it a nuisance. It seemed to the Court that the finding of the jury on the second issue was not satisfactory, and that shook the confidence of the Court on the finding of the jury on the first issue. So it would be better to send the case down for a second trial, with the direction of this court that the specific question should be whether the hospital constituted a real source of danger or not. The rule for a new trial was then made absolute, the question of costs of the former trial being reserved.

CARPENTERS should remember that fresh glue dries much more readily than that which has been once or twice melted. Dry glue steeped in cold water absorbs different quantities of water, according to the quality of the glue, while the proportion of the water so absorbed may be used as a test of the quality of the glue. From careful experiments with dry glue immersed for twenty-four hours in water, at sixty degrees Fahrenheit, and thereby transformed into a jelly, it was found that the finest ordinary glue, or that made from white bones, absorbs twelve times its weight of water in twenty-four hours; from dark bones, the glue absorbs nine times its weight of water, while the ordinary glue, made from animal refuse, absorbs but three to five times its weight of water.

ACCORDING to the Des Moines (Iowa) *State Register*, an architect of that city "is engaged on plans for the highest church in the world, at Naina Tal, India. It is to stand on the Himalayah Mountains, on a point 6,500ft. above the level of the sea. The directions state that the rainfall there is from 100 to 110in., and consequently the building must have wide projecting roofs and verandas, but no heating apparatus. The details are curious, as showing the difference in climate between that distant land and our own."

A new and important discovery is reported to have been made by M. Mery, a Frenchman, which, if it prove to be true, will be valuable to the painting arts and trades. He has been experimenting a great many years, and he claims now to have hit upon the means of making and applying imperishable water-colours. He does not explain what he uses as a vehicle for his pigments, but it is something which, while it will mix with water, is not soluble in it. Whatever it is, it renders the colours unalterable, and, as it becomes after a time as hard as cement or stone, they may be said to be indestructible. It

can be applied to any surface suitable for ordinary oil or water painting, such as wood, paper, glass, stone, canvas, &c., and can be prepared so as to dry in a few minutes or remain moist for an indefinite length of time. It is suggested that possibly M. Mery has rediscovered the long-lost art of encaustic painting, which is supposed to have been applied and fixed by means of heat. It seems almost incredible that a paint can be applied by means of water, and yet not be affected by it afterwards.

At the last meeting of the Boston Chapter of the American Institute of Architects, some letters from Joseph T. Clarke, junior member, were read, reporting progress in the prosecution of his archaeological researches in Europe concerning the Greek Doric Order, undertaken mainly under the auspices of the Chapter. The views of Mr. Clarke regarding the manner of lighting the Greek temples are entirely at variance with those now generally accepted by archaeologists. He argues that there is no sufficient authority, either in the remains themselves, or in the texts of ancient authors, or in medals, coins, or models, to sustain the theory of an opening of any kind in the roofs of the temples; that the famous passage in Vitruvius, upon which the whole hypothetrical theory is based, is at best obscure, and that the testimony of this author is not conclusive in regard to questions of Greek art; that the chryselephantine statues and the treasures of art accumulated in the temples were not of a nature to sustain the changes of temperature to which they would have been subjected by an opening to the outer air; that the genius of the Greeks was opposed to the use of such elaborate mechanical contrivances of shutters, &c., as must have been needed to exclude the rain and dampness from the interior; that the mystery which was a part of the hieratic system in the worship of the Greeks, as of the Egyptians, would have been far more effectively sustained by the light of lamps and torches than by the familiar light of day; that the example of the Roman Pantheon has no bearing upon the present question; that the structure of the Greek Doric temple is such that no light could be introduced through the roof without leaving large dark spaces in the area within; and that Mr. Fergusson's hypothesis of a clerestory is foreign to Greek methods, and is not in accordance with the text of Vitruvius.

It is announced that an exhibition of sanitary appliances at Cork, in connection with the annual meeting of the British Medical Association, which is to take place in the Queen's College, Cork, from the 5th to the 8th of August, 1879, an exhibition of sanitary appliances will be held in the new Palm Houses, and opened to the public during the visit. An address in the Public Health Department will be delivered by Dr. Andrew Fergus, President of the Faculty of Physicians and Surgeons, Glasgow, on Friday, August 8th, 1879. Intending exhibitors are invited to apply to Arthur Hill, at 22, George's-street, Cork, without delay. No applications can be received after June 30th, 1879.

THE Royal Institute of British Architects has been invited by the Prince of Wales, acting as President of the Royal Commission for the Australian Exhibitions, to co-operate with the Commissioners, with a view of securing at Sydney and Melbourne such an exhibition of architectural drawings as may maintain the reputation of British Art. Forms of application for space should be obtained of the secretaries of the Institute without delay, as the drawings to be exhibited must be at once collected and despatched. Should the applications for space exceed the amount of space disposable, and should it be necessary on that or any other ground to make a selection from the drawings offered, the council will act as a committee of selection.

The fifty-first election of pensioners on the funds of the Builders' Benevolent Institution took place on Thursday, at Willis's Rooms, St. James's; Mr. George Dines presided. There were five candidates, three men and two women, and there were vacancies for two men and one woman. The candidates were Gregory Bartlett, aged 75 (second application), Thomas Frederick Cook, aged 59 (first application), Jeremiah Bromley, aged 68 (first application), Susan Gulson, aged 62, widow of Thomas Gulson (second application), and Mary Ann Hibberd, aged 64, widow of Daniel Hibberd (first application). Shortly after three o'clock the scrutineers (Messrs. Thos. Stirling and T. F. Rider) announced the result of the voting to be as follows:—Cooke, 4,504; Bartlett, 3,035; Bromley, 1,077, plus 75 votes added in accordance with the rules of the Institution, to which the applicant was a subscriber for thirteen years, making a total of 1,152; Gulson, 1,561; and Hibberd, 896. The chairman therefore declared the successful candidates to be Thomas F. Cooke, Gregory Bartlett, and Susan Gulson. Votes of thanks were accorded to the scrutineers (on the motion of Mr. Cruttenden, seconded by Mr. New); to the vote-checkers (on the motion of Mr. Rider, seconded by Mr. Richardson), on whose behalf Mr. Simpson replied; and to the chairman (on the motion of Mr. Bussell, seconded by Mr. Rider).

CHUBB'S

WROUGHT IRON DOORS,

Fire and Thief-Resisting Strong Rooms, Safes, and Iron Linings

THREE PRIZE MEDALS

And HONOURABLE MENTION AT PARIS EXHIBITION, 1878.

Illustrated Price Lists post-free.

CHUBB & SON, Makers to the Bank of England,

128, Queen Victoria-street, St. Paul's, E.C.; and
66, St. James's-street, Pall Mall, London.—[ADVT.]

The erection has just been completed in Bolton of a cotton mill in what is described as a novel style of architecture. It is six stories in height, and the dimensions of each room are 143ft. by 100ft. Instead of the usual brick divisions between the windows, light iron pillars have been used, the result being that the building appears like a vast glasshouse. It is not uncommonly spoken of as the "Crystal Palace."

THE ARTIFICIAL MARBLE COMPANY

(DELAROCHE'S PATENT).

MANUFACTORY AND SHOWROOMS:—VYNER STREET, CAMBRIDGE ROAD, LONDON, E.

ARTIFICIAL MARBLE MANTEL-PIECES, { MADE IN SICILIAN, VIOLET-VEIN,
ROUGE, ST. ANN'S, &c.

CHIPS.

An International Congress was held in Paris on the 15th inst. under the presidency of M. de Lesseps, to discuss the question of cutting through the Isthmus of Panama.

A Local Government Board inquiry was held at Bournemouth on Thursday and Friday week, before Mr. J. Thornhill Harrison, C.M., with respect to an application from the Bournemouth Improvement Commissioners for sanction to borrow £19,200 for works of sewerage and for an esplanade, and of £350 for public urinals. The plans have been prepared by Mr. C. C. Creeke, till recently consulting engineer to the Commissioners.

An inquest was held at Beeston, near Nottingham, on Monday, on the body of Charles Glasbrooke, who died from the effects of injuries received by falling from a scaffold on the previous Wednesday. The contractor, Mr. Oakley, was censured for the condition of the scaffold, which the jury regarded as insufficient, but a verdict of Accidental Death was returned.

Messrs. Chatto and Windus announce as ready for immediate publication "Church Work and Life in English Minsters, and the English Student's Monasticism," in two vols., with map and ground plans, by Mr. Mackenzie E. C. Walcott.

Owing to the suspension of Swann, Clough, and Co.'s bank, the restoration works at York Minster were stopped on Friday last.

New schools are about to be erected for St. James's parish, Darwen, consisting of large mixed school, two infant-rooms, and four class-rooms. Accommodation is provided for 600 scholars. The designs have been prepared by Mr. W. Perry, architect.

A new Conservative Club is to be built in Darwen, which will contain on the ground-floor, private billiard-room, ordinary billiard-room, reading, committee, manager's, secretary's, conversation, and smoke rooms. The second floor will be in one large room for lectures or concerts. Mr. W. Perry is the architect.

Herr Semper, the architect of the Dresden Theatre, who was considered the greatest living German architect, died at Rome on May 15th in his 77th year.

The Bishop of Peterborough presided at the anniversary festival of the Artists' General Benevolent Society, which took place in Willis's Rooms, on Saturday last. He spoke of the influence of art upon himself, who professed to know nothing about art; but this, he said, was a feeling common to both rich and poor. To the needy brethren of the chisel, brush, and pencil he held that the public, to whom so much innocent and elevating pleasure accrued from artistic labour, should extend their timely assistance.

MEETINGS FOR THE ENSUING WEEK.

TUESDAY.—Society of Arts. Paper by Edward Hinton on "The Contact of Civilisation and Barbarism in Africa Past and Present," 8 p.m.

THURSDAY.—Society for the Fine Arts. Lecture by Robert W. Ellis on "The Furnishing of Town Houses," 8 p.m.
Civil and Mechanical Engineers Society Annual Meeting.

FRIDAY.—Royal Institution. Grant Allen on "The Colour Sense of Insects: its Development and Reaction," 9 p.m.

Holloway's Pills.—Typhoid and other Fevers may be arrested in their early stages by a course of these purifying Pills. This medicine controls the circulation, lessens the shivering, and modifies the hot periods. Holloway's Pills relax the parched skin, diminish the excessive thirst, clear the furred tongue, and restore to health.

WAGES MOVEMENT.

BARNSELY.—The dispute between the master builders and the masons, labourers, and quarrymen, which has now lasted some weeks, with respect to a reduction of wages and longer working hours is still unsettled. On Tuesday, night a largely attended meeting of master builders was held. A deputation from the men attended and laid the views of the men before the meeting. A lengthy discussion took place with regard to the pending reduction of wages, the masters having given notice in the first instance that the men should work at 7½d. per hour per day, and also work half-an-hour extra per day. The deputation offered to submit to 8d. per hour and work 49½ hours per week, and be paid by the day as before. After a long discussion the masters resolved that in order to bring about an amicable arrangement they would take 7½d. per hour, and allow the men to work the same hours as before, viz., 49½ hours. The deputation not being empowered to make any such concession they left the meeting, and promised to lay the matter before the men. This was done on Tuesday night at a meeting of the men, held at their lodge-room, when no resolution was come to to accept the master's terms. Another meeting was held at the lodge-room on Wednesday, but no arrangement was arrived at.

LIVERPOOL.—An aggregate meeting of plasterers' labourers was held on Tuesday, for the purpose of "considering the recent arbitrary action of their employers in reference to wages and hours of labour." The Chairman read a draft letter which it was proposed to send to the master plasterers on behalf of the labourers. It set forth that the employers had not acted towards the men with their usual courtesy by reducing the wages and increasing the time of labour by 5½ hours without giving any notice of the change, and asked that a deputation from the men should be received by the masters with a view to the recent alterations being reconsidered.

PENRYN.—The threatened strike at the great Penryn slate quarries, Carnarvonshire, was settled last week, by the acceptance of a reduction in wages of about half-a-crown—the men to continue working four days a week. The slate trade of North Wales continues in a very depressed state.

WIGAN.—At a meeting of the master builders of Wigan and the joiners and carpenters last week, in reference to the proposed reduction in wages, an arrangement was come to whereby the men are to be paid 7½d. per hour and the week's work consist of 54½ hours, this being the basis of the award in the arbitration with the painters, plasterers, and

bricklayers. The notice by the masters was for 7d. an hour and 54½ hours per week. The masons and plumbers still remain on strike, both of these classes strongly objecting to the increase in the number of working hours.

Douling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to

CHARLES TRASK,

Norton-sub-Hamdon, Ilminster, Somerset.

Agent: Mr. E. CRICKMAY, 4, Agar-street, London, W.C. —[ADVT.]

TENDERS.

BUNTINGFORD.—For the erection of national schools for girls and infants, Buntingford, Herts. Mr. T. Tayler Smith, architect. Quantities supplied:—

	Entire school, brick and flint.	Entire school, brick.	Girls school only, brick.	Girls school only, flint.
Chinnock ...	£1,361	£1,376	£1,261	£1,260
Cates ...	1,216		890	
Saint and Son ...	1,145	1,177	826	839
Prout ...	1,110	1,130	819	827
Lawrence ...	1,030	1,030	790	820
Seales and Norris ...	954	993	674	667

BARMOUTH.—For main sewers for the Barmouth Local Board. Mr. Thomas Roberts, Portmadoc, engineer:—

Frithard ...	£690	0	0
Tabiner ...	650	0	0
Marrow ...	610	0	0
Weyman ...	612	0	0

THE BUILDING NEWS.

LONDON, FRIDAY, MAY 30, 1879.

THE STONE-YARD OF FRANCE.

THERE is no material in existence representing a greater variety of quality, use, and substance, than stone, though a history of it, in its innumerable applications, has never been written. The effect of its presence, in, or absence from, a country, is of course, most marked in the architecture, and even the manners of the inhabitants, and this has been nowhere more apparent than in many parts of England, including the metropolis. But to few territories of Europe is the stone supply so important as to France; though even the French, with their abundant command of the material, have made frequent failures in building, owing to the defective character of their quarries. Thus, the Palace of the Institute, at Paris, within a few years of its erection, began to exhibit signs of hopeless decay; though, as a parallel fact, it must be admitted that even the tomb of Napoleon, originally supposed to be among the most perfectly elaborated structures in the world, is being eaten away by that which French naturalists describe as a species of stone spider. This uncertainty with respect to the solidity of the public buildings erected of stone wrought from their own quarries, led the French architects, so far back as 1678, to insist upon a report on the subject from the Royal Academy of Architecture at Paris. It was found that some were suffering from what was called "stone disease"—*mal de la pierre*—a term afterwards applied to people with a mania for building; others were so soft as to be actually flexible; a few were spongy, and required to be solidified by artificial processes; and many could not withstand the action of rain. Such was the statement made, on high professional authority, two hundred years ago. A good deal of practical knowledge, connected with the whole matter, has no doubt accumulated since then; and we possess, indeed, a set of documents in which the entire stone-producing capacities of France are reviewed—from the yield of Changelade, harder than the Egyptian rock, to that of Crupol, pliable as "Calcutta marble;" from that of Coirtenoux, resembling exactly the lava of which the Chiamonte Palace at Palermo is constructed, to that of Vergelée, which supplied materials for the new staircases at Versailles. A curious circumstance is that this latest report coincides precisely with one that was drawn up in 1680, concerning the churches of Blois, St. Victor, and Menar, the descriptions of the stone being the same—tender, easily wrought, capable of an exquisite finish, but destined to early decay, as is evidenced by a multitude of dilapidated edifices in the valley of the Loire. The stone, again, of Apremont and of Charite has not changed its reputation in the least, but is still invariably in demand where deep foundations have to be laid for the sustaining of ponderous superstructures. Thus, moreover, we find the ancient quarries beneath the Faubourg St. Jacques, in Paris, represented to this day by most of the antique hotels in that quarter; while, on the other hand, for the construction of their bridges, the Parisians have immemorially resorted to the hard and finely-grained rocks of the Jura. But, for the kerbs of their canals and the masonry lining their gutters, the French builders have generally preferred to employ stone from Coirtenoux or Monasse, on account of its being, at the same time, porous and durable, the same reasons explaining its large use in the exterior cornices of houses;

though often, after a few years, this material exhibits on its surface a sort of efflorescence rapidly converted into decomposition. An examination of monuments, two centuries old or more, has also aided the official investigators in determining the permanent value of the various quarries in France. Many they found intact, and these in Paris were built, for the most part, of the stone which French builders call *Liais*, abundant beneath the metropolitan faubourg of St. Jacques, at Chartreux, and the environs of Arancil and Creteil. It is not merely used for foundation walls, but also for chimney-heads, coping-stones, gutters, balustrades, columns, the pavement of crowded crossings; it can bear almost any amount of wear and weight, and can only be wrought into shape by the most powerful tools. The Holy Chapel, at Paris, constructed entirely of this material, is to this hour without a flaw, except where the iron clamps have rested. But in the Cathedral of Notre Dame itself, with the same substance employed, only in parts of the edifice, however, by the architects, a singular result has been obtained. Those surfaces which are exposed to the air betray few signs of decomposition, while those of the interior, acted upon by neither air nor rain, are worm-eaten, so to speak, to a lamentable extent, reduced to an extreme thinness, and even worn, here and there, as in the pavement, into holes. This is explained by the extraordinary fineness of the pores, the water which penetrates the exterior surfaces being easily evaporated, through the action of the atmosphere and the sun, and it is remarkable that the decay is more rapid on those in the interior where they are laid on beds of mortar. The solid brown-tinted stones of the Burgundy quarries are therefore recommended for this kind of work, rather than the whiter qualities of, for example, St. Leu, full of salt-petre, chalk, and sand, which are beautiful for a time, but speedily crumble, like what are styled "the rocks," or "mill-stone rocks" of Paris—very valuable for foundations, but worthless for building in the open air. Much of the stone in the rocky basin of Paris presents similar peculiarities; it can bear rainfalls in any degree; but it yields to anything like a continual drip. For pinnacles, cornices, crests, and roof decorations generally, we are told, the quarries of the Oise Valley are incomparable, with their blocks of porous, sonorous stone, which are difficult to chip, and never wear away in scales; which absorb quantities of water while lying in their natural beds, and eject it upon coming into contact with the atmosphere, forming a kind of crystallised casing for themselves, of considerable importance to the builder, if advantage be immediately taken of it—preventing, as it does, the process called "death," to which so much of the stone found in France is liable. The French capital, of course, has long been dependent, in a large degree, upon the provinces for its supply of building materials, and these are brought, by canal for the most part, in enormous quantities from Soissons and Chatillons, from the Manse, Dornecy, and Ravieres, the latter being especially prized for the dimensions of its blocks, their durability, equality of grain, and uniformity of surface. That of Soissons is heavy and takes an exquisite polish; the "rock of Farget," almost resembles marble, and is in great request for stairs and steps.

The objects of the inquiry, now still going forward, include the general amount and probable duration of the supply—for that quarries may be over-worked to a dangerous degree is demonstrated by the example of Paris itself—the resisting power, both as to crushing, as to damp, and as to atmospheric influences generally; knowledge of the highest importance, say the authors, both to the architect and to the practical constructor. Next in order rank the grain

of the stone, the local processes of quarrying, and illustrations of its local employment, with the dates of the various edifices in which it has been used, and their condition at the present day. The inquiry instituted by Colbert, as we have said, in 1678, resulted in a report of 125 sections; that now in progress will probably double the number. The French naturally set great store by their supplies of stone, and point to England as an instance of a country without a sufficiency of this material. They dwell upon the construction of our castles, which, grand though they were, consisted chiefly of heaped up pebbles and mortar, and affirm that the basement of Westminster Abbey itself rests upon no more than a foundation of concrete. Yet they are themselves fain to confess that a good deal of what passes for stone in France is little better than a sort of white or yellow chalk, or, as it were, petrified clay, from which porcelain is made, though it is easily worked into temporary building forms, great quantities of this being used up in the Parisian suburbs, from the valleys of the Loing and Yonne, as, of course, it is far cheaper than the solid substance, still be excavated at Courtagnon, near Rheims, and even Grignon, near Versailles, whence were obtained the materials employed in the construction of their masterpieces by Lamarch and Deshayes. Similar, though superior, are the so-called "stone pits" along the banks of the Marne, at Champigny, at Montmorency, and at Beaune. When, however, we are to compare these doubtful productions of the soil with the tomb of Napoleon, though even that has not escaped the first symptoms of ravage, it must be remembered that this is by no means exclusively French. It is true that Italy, Greece and Egypt failed to supply the mass of porphyry that was wanted; but the principal block, after all, came from the unexhausted quarries of a northern region. France, however, as we are reminded, possesses valuable treasures of this description. There are both red and white porphyry in the Vosges mountains, in the valley of the Loire, near the town whence Chateaubriand took his title, blue porphyry in the Var, the kind known as basalt porphyry in Auvergne, the green qualities in Brittany, the gray at Metz, and the yellow in three or four departments beyond the Marne. In fact, an idea may be formed of the riches possessed by France in her quarries from the digest prepared by M. Hélicart de Thury, for the information of the Government Commission. He shows that in 80 French departments marble, in more or less excellent quality, is found; while red, black, green, brown, violet, blue, and amber porphyries are obtainable from no fewer than 30. Perhaps more valuable than either is the stone known to French architects as *vergelée*, exceedingly solid and heavy, excavated in immense abundance at St. Maximin and St. Leu, of which were built in great part the famous Chateaux of Gaillot and Anet, and the magnificent Cathedral of Rouen, and of which several cargoes were exported across the ocean to assist in building the Imperial Palace of Brazil, at Rio Janeiro. The inquiry, however, ranged to artificial as well as natural stone, and some points in connection with this are of interest. It is shown that sundry well-known monuments, generally believed to be monolithic, are actually composed of "granite paste," a substance which defies the weather for an extraordinary length of time; yet this is a topic apart, and does not directly bear upon the riches in stone scattered over the French territory. It is a fortunate circumstance for the internal trade of the country that neither the demand nor the supply are ever purely local. Of course, the peasants everywhere construct their cottages of the materials readiest to hand, so the character of the neighbouring quarry imprints itself upon the abodes of the people

for miles round in every stone-working district; but certain kinds, only to be found in particular localities, have a special value assigned to them in the building of belfries and church towers. That of Vineuil is sought for to be employed in ornamental pavements; that of Vidy for the lintels and jambs of doors and gates in large country houses; that of the Jura, as we have observed, for bridge-building, in Paris particularly; and that of Clignancourt for cisterns, or wherever the action of water has to be continuously sustained. France, it is to be remembered, possesses very little slate—none at all, it may be said, of the first quality, though the quarries of Agens yield considerable quantities for the roofings of chateaux, turrets, and wherever the Louvre style is adopted. Lead, however, has of recent years been extensively adapted to this purpose, though by French architects, it is almost universally disliked. It is not even attempted, even by those who have been submitting the whole subject to analysis, to suggest an approximation to the actual value of the French stone, marble, and porphyry quarries in the aggregate. It would be like taking stock of the English coalmines. But they may be regarded as being, taken for all in all, practically inexhaustible, and there can be no denying the influence they exert upon both public and domestic architecture in France. Their variety is as great as their range is unlimited, and there is not a cathedral, palace, municipal edifice, ancestral mansion—scarcely a house in a town, or a hamlet in the country—but what testifies to their existence, and to the large part they play in the national life. France, so to speak, lives in a house of stone built out of her own soil, which accounts for a thousand characteristics visible to the traveller.

THE WESTMINSTER INDUSTRIAL EXHIBITION.

FROM a small and humble commencement made last year, the Westminster Industrial Exhibition has this year grown to dimensions that bespeak the success of the enterprise. The idea of an artisan exhibition that shall become an incentive to good workmanship, industry, and inventive skill, and which shall, by prizes judiciously bestowed, offer an inducement to the working man to employ his spare hours with intelligence and profit is itself undoubtedly excellent; though we think there is one possible danger to be guarded against by the promoters of exhibitions of this sort, namely the extolling of mere mechanical labour at the cost of intelligent thought and art skill. There is frequently the mistake made of rewarding the exhibitor's manual dexterity, his capability of turning out models of buildings and steam-engines, in which every feature and screw are reproduced with marvellous fidelity and minuteness, or the laboriousness and patience spent upon a piece of inlaid work in which the design has been made a secondary consideration. We certainly object to anything which may have the effect of making men skilled automata rather than thinking artists. The exhibition at Westminster is largely made up of objects contributed by artisans and amateurs. Of course both kinds of industry should be encouraged within certain limits, and it is the need that both should be placed upon their own merits that have prompted us to the above remark.

As we have already spoken of the very effective temporary buildings erected in Victoria-street from the designs of Mr. John P. Seddon, the honorary architect, we may now take a rapid glance at the show, which was opened last Saturday afternoon by the Speaker.

Of the varied and rather heterogeneous collection the "mechanical" almost neces-

sarily occupies a very large portion, comprising such objects as cabinets and inlaid tables, wood and ivory turning, musical instruments, cane work, models of steam-engines, carriages, buildings, &c. In this department we notice some excellent specimens of cabinet work, evincing technical skill of a high order. We are struck with bookcases, inlaid tables, and fancy boxes of a kind that compete with many of the best productions in the trade, though here, as in other classes, the difficulty is to distinguish fairly between the work of professed workmen and amateurs. We notice a bookcase of pollard oak, by G. Bates, with traceried panelling of Late Gothic, excellent in workmanship; a workbox (No. 18); tables and stools (No. 29); a satinwood jewel-case (56); an elegant inlaid pier-glass frame (58), in which both the form and inlays of tulipwood and walnut are commendable; a work-table (46), all being the works of carpenters and cabinet-makers. Nos. 53 and 84 are both pleasing cabinets; and so is 61, an overpiece in walnut. The work as a whole of this kind is certainly much in advance of previous efforts. In style and design there is more taste displayed, if even yet that taste seems to lack expression and the refining influences of art instruction. The faculty of pains-taking is indeed prominently manifest, the one want being intelligent meaning and self-reliance. No. 83, a specimen of "double quadruple dovetailing," &c., is an exceedingly skilful piece of joinery, in which no effort is made beyond the mechanical, and we can appreciate the labour and industry at its full value. More numerous are specimens where the motive of the workman is not so apparent, where neither use nor beauty is aimed at except a sort of unmeaning desire to show a trickster's cleverness. These comprise puzzle-boxes and other ingenious but useless kind of models. As an instance we notice No. 545, a large shellwork model of a cathedral front, composed entirely of shells, by G. Mawson, plasterer, which has taken its author 34 years, being begun in 1842. It is intended as a bird's nest! Extremely interesting as an example of plodding patience and untiring industry, we must yet deplore the waste of skill and time over a useless object no less purposeless in its intention. The thought strikes one how much more usefully the spare moments of the 34 years might have been spent. Very different is such a model as No. 211, to which the judges have awarded the gold medal, namely, a locomotive engine and tender, by R. Arkwright, of Herne-hill; or those models illustrative of apparatus for saving life from fire and at sea, Nos. 491 and 492, 498, 500, 504; for railway brakes, or those showing improvements in casement and sash-fastenings, in kitcheners to roast by reflection, as in 343. We note several ingenious models, such as 509, a recording thermometer to register by electricity; a chronometer escapement, 521; but we pass on to notice the products which fall under the head of "Artistic." In ivory and wood turning are to be seen many clever specimens. We note No. 103, a turned bowl, oval in shape and well-moulded; some frames and medallions in boxwood (133) by a carver's apprentice; an over-mantel (138); Bacchante's heads and a girl's head in relief, No. 154. In terra-cotta, H. Gunthorp, in 561, sends some clever and spirited specimens of modelling. We notice "Samson Slaying the Lion" as especially vigorous, and a few cleverly carved stone circular panels with animals (593); but, as a rule, despite the evidence of industry, the work in this class falls from the evident desire to produce something skilful as a piece of handiwork only, without an insight into the first principles of modelling in relief, or a due regard for outline and composition in plastic art. The vases, fountains, brackets, and statuettes generally evidence technical skill, but nothing

beyond. In the marble exhibits the same fault pervades the objects, and the commonplace and misdirected invention are predominant. Painting on glass and china has received some attention. No. 909, hand-painted plates and tiles show some tasteful designs. We note a few plates in which plants are introduced in the Japanese style, one by F. G. Malins. No. 906, china plaques, by Mary Dentone, of Lordship-lane, are very good examples; and another, in which lilies are painted upon plates, by Mary Glossop (1560). We notice also 924. A few good specimens of glass-staining are to be seen. Turning to architectural designs, we find this class of work is not numerously represented, though a few exhibits call for remark. We observe especially a series of working drawings by students of Nine Elms, Southwark, Stepney, Greenwich, and other science schools, which have been done under the guidance of Mr. Parton Parry, displaying considerable merit and technical knowledge. Mr. A. T. Broadhurst also contributes eighteen drawings. We may mention geometrical elevations and sections (coloured) of Tenterden Church, Kent, executed by the Southwark Science Class, as careful delineations of measured work. No. 873 shows a coloured design for a residence by E. Daymond, builder's surveyor, of more than usual merit. It is of red brick, with stone dressings, in the Italian style, the chief fault being a rather heavy and lavish use of ornament round the windows. Among other exhibits we note a design in monochrome (874) by G. J. Daymond, architectural sculptor; three designs by H. Edwards, draughtsman; water-colour designs for interior decorations, by A. E. Lowe (890); an arabesque over-door; drawings for tile floors; design for a country residence, by T. Sims, architect's assistant; brickwork details; a series of 20 well-executed drawings, by J. Woodley, bricklayer, clerk of works, Brixton, showing construction of niche and ornamental brickwork; another set, by F. Stocker; designs for workmen's dwellings, by F. Witt, clerk; drawings by J. Taylor, draughtsman, &c. "A design for church," coloured, like many other of the designs, exhibits the usual ambition, and redundancy of ornament is the besetting vice. We observe, in looking over the catalogue, several designs have been contributed by other than architects' assistants, one exhibit being by a merchant's clerk. Oil and water-colour paintings make a rather large class, though the exhibits are unfortunately mixed up with other work which rather distracts the eye for picture viewing. We have oil-paintings by opticians, newsagents, stone-masons, letter-carriers, carpenters, commercial travellers, and bill-posters; so it is certainly one of the departments which have not been wholly given up to professional experts. Mr. H. Major takes the first, and Mr. Gare, a jeweller, the second, prize in this department. Some of these exhibitors are very prolific; thus, there are three oil-paintings by W. H. Ball, newsagent, and no less than eight by T. W. Colley, a harness-stitcher; in these, as might be expected, enthusiasm and a mistaken zeal for art are the chief recommendations. As examples of untalented talent which our schools have not reached, some of them exhibit decided ability, and the only regret we feel is that so much labour has been expended without direction. In the water-colours we notice No. 726, a river piece, by E. Ferris, designer, who wins the first prize. This is a carefully-executed drawing, and there are several others that display considerable feeling for colour, though the work of men of very humble position. The chief faults observable in this department are imperfect drawing and perspective, and a garish sense of colouring, that only requires the training of a school or a good master to correct. The pen and pencil drawings are very numerous;

the exhibitors are from every rank of life, from the artist to the dock-labourer. It is impossible to estimate the actual art capacity of any exhibitor when many of the drawings are the works of draughtsmen on wood and professional artists. Illuminated texts and specimens of ornamental writing are, as usual, in abundance, but we especially note 961, "A Manuscript Book on the Antiquities of Kent," by W. Dampier, a clerk, of Bermondsey, containing 420 pages of closely-written description, interspersed with 300 sketches in sepia and pen-and-ink—a work of credit and of immense labour. We can only further notice some specimens of graining and marbling, some excellent goldsmith's metal work, a few flower-boxes and aquaria. Of the last, Nos. 1,034, 1,037, and 1,044 are pleasing combinations of both, while the ladies' department in embroidery and needlework must not be overlooked by the visitor, numerous specimens of wool pictures and flowers, crochet and knitting enlisting attention for the unsparing labour and, in some cases, taste they display. The arrangement of the area and the covering of the central space by a series of three parallel canvas buildings produce quite a bazaar-like effect, and we are sure those who have any doubt about the industry of the working man will be agreeably disappointed by a visit to the Westminster Exhibition. The one impression the show leaves upon us is that the art teaching of our schools of design has something more to accomplish in reaching the class of workers who contribute to these exhibitions—at present the only step they possess towards advancement. We have indeed ample raw material, skill and industry, awaiting only direction and aim.

JOHN B. PAPWORTH, ARCHITECT.*

AN interesting chapter in the history of the architectural revival has been reopened by the publication for private circulation of a memoir of the life and works of the late John B. Papworth, architect to the King of Wurtemberg, by his son, Mr. Wyatt Papworth; and we have pleasure in laying before our readers a few incidents in the career of a man who in his time and generation contributed not a little towards that revival of taste which has culminated in our own day. Mr. J. B. Papworth, the father of the respected firm of architects who for a long period carried on together the business left to them, but of which now only one member remains, commenced his career in the same profession at the beginning of the present century, or rather saw the last decade of the 18th, and the first half of the present century. We may just glance at the circumstances of the period so eventful in the history of the arts. Mr. Papworth began to study his profession when Sir William Chambers, Sir J. Soane, Sir Robt. Smirke, and Mr. James Wyatt were in practice, and was connected with the first and last architects. The Greek revival had just begun to make its influence felt, while Mediaeval art was also beginning to exert an enthusiasm in another direction. Mr. Papworth followed the Italian, and was one of the first of the Greco-Roman school. Intended for the study of surgery, which he gave up from a strong predilection for architecture, we are told in the autobiographical sketch that this bent was determined by a visit to the little theatre in the Haymarket, where there was at that time (1787) a drop-scene, painted by Michael Angelo Rooker, of a Corinthian colonnade and court of a palace. Being the first glimpse the young Papworth, then a school-lad, had of a theatre, the sight struck him so much

that he drew it on the next day, and as he was finishing it Mr. Wilton, the sculptor, was so pleased with it that he took it to Sir William Chambers, and on the following day he accompanied the boy and his drawings to Sir William, who was then living in Berners-street. After this Sir William became a friend of young Papworth, lent him drawings to copy, and it was by his advice that the youth was placed under the tuition of Mr. John Plaw, an architect, during which time he was instructed in the art of perspective by Mr. Healy. The study of the human figure also engaged the young student, who received lessons from Mr. John Deare, sculptor, a gentleman sent to Rome by the Royal Academy, and accompanied M. Rossi, both being recipients of the medal that year. At the age of fifteen, we learn, young Papworth was skilled in architecture and perspective, ornament, the human figure, and modelling. These art requirements were supplemented by a practical knowledge of construction and building, which he learnt from Mr. Thomas Wapshott, an eminent builder with whom he was placed for three years. At this period (1788) Covent Garden Church was repaired, and in 1795 it was rebuilt, from Mr. T. Hardwick's designs, by the same builder. "During this time," to quote the autobiography, "Mr. Papworth sent several drawings to the Royal Academy exhibitions"; and before his term had expired he was induced to study internal decoration and fresco work, then lately introduced from France by Mr. Sheringham, of Great Marlborough-street. After this Papworth became clerk of works during the erection of a residence built for Sir James Wright, Bart., at Woodford Bridge, Essex, called Ray Lodge. These incidents in his earlier life we have taken from the autobiography to which we refer our readers, and we may gather from the above particulars that the education of the architect at this early period was far more perfect than it is now. It is worthy of remark that architecture has been the hereditary profession of the Papworth family. Mr. John Papworth (the father of the subject of this memoir) was a master plasterer and stuccoist—one of the tradesmen of the Office of Works—and was called by his numerous staff of workmen, "architect, plasterer, and builder."

Paddington Church is one of the executed designs of Mr. Plaw, the master of John Buonarotti Papworth, and it is surprising that an architect of the undoubted taste of the subject of this memoir should have been his pupil. The sources of his architectural instruction and inspiration, were doubtless a self-acquired taste, founded upon such works as Stuart and Revett's "Antiquities," Nicholson's "Architecture," Alberti's and Chambers' treatises, and the abridgments of Palladio then extant, though no doubt the works of his friend, Sir W. Chambers, and other eminent architects of the day, had a considerable share in helping to form his taste. Mr. Papworth lived for a time at 30, Great Portland-street, the residence of his father; he then took a house in George-street, Adelphi, and subsequently resided in 6, Bath-place and Caroline-street, Bedford-square. He married a daughter of his former master, Thomas Wapshott, but soon became a widower, afterwards marrying the eldest daughter of William Say, mezzotinto engraver, herself a skilful musician and artist. The "experiences" recorded by one of Mr. Papworth's pupils, Mr. James Thomson, while in his office, fill up an important gap in the career of this architect. We find Mr. Papworth here spoken of as a distinguished exhibitor in the Royal Academy, and in the Architectural room at Somerset House, and several of his earlier works are noticed. Among country residences we find mentioned the villas for Sir David Wedderburn, at

Chigwell; for Mr. George Dorrien, Mr. Burnmaster, and other City magnates. He also designed the Earl of Lucan's house near Staines, the engineering factory for Mr. Alex. Galloway, in West Smithfield; a house for Mr. Herries, banker, the garden-seat at Claremont for John W. Hiert, afterwards converted by Prince Leopold of Saxe Coburg, a mausoleum erected by Whitelaw at Knebworth, the residence of Sir E. Lytton Bulwer. In 1813 his artistic talent was employed in the building of the large room at Mr. Ackermann's house of business in the Strand, which was a repository of art; but his most complete works were Leigham House, Montpelier Spa, Harley-street, and Basildon. The Harley-street improvements and decorations made for Mr. James Morrison in 1831 brought Mr. Papworth's ability and taste as an artist in decoration prominently into notice. The rich caissoned ceiling of the gallery of the first floor, the library and its fittings and furniture, were for the time models of elegance, and it was at this house Mr. Morrison, then M.P., received the council and members of the Institute of British Architects at a conversazione in July, 1840, Mr. Morrison having become an honorary Fellow on his architect's recommendation. Evidence is not wanting to show that Mr. Papworth was a thoroughly conscientious architect, scrupulously particular in the forms of his mouldings and the carvings and modelling employed in his work, all of which he required to be submitted to him before approval. In 1829-32 we find him engaged in the design of alterations, at Holt in Norfolk, of a Domestic Gothic residence for Charles Nevill; and in 1830 he modernised the mansion at Cally in Scotland, for Alexander Murray, of Broughton, son-in-law of the Earl of Lucan—one of Mr. Papworth's best works. He was continuously engaged in the design of works of decorative character, garden accessories, fountains, conservatories, furniture, which we cannot particularise here. Mention is made of his employment at Fonthill; and we find him in 1838 engaged in modernising and decorating "Basildon" for James Morrison, formerly the seat of Sir Francis Sykes, Bart., and originally designed by John Carr, of York. Mr. Papworth was one of the first who promoted a professional society which ultimately developed into the Institute of British Architects, and in 1847 his admirers and professional friends presented to him on his retirement from practice a silver inkstand as a "tribute of respect and esteem for his talents as a distinguished architect, and for his worth as a man." This is signed by all the leading architects, including T. Allason, Charles Barry, R.A., T. Bellamy, C. R. Cockerell, R.A., T. L. Donaldson, &c., &c. Professor Cockerell presented the testimonial on Mr. Papworth's seventy-second birthday in a speech of some length, in which the reasons which prompted the presentation are dwelt upon. In this speech Mr. Papworth's reputation in a practice of fifty-five years for delicacy and purity of taste is spoken of; also his zeal as the promoter of the Government School of Design, and his endeavours to promote the union of landscape gardening with architecture. Among his pupils we find the names of Samuel Benwell, who died early; his own brothers, George and Robert Papworth; James Thomson, William Adams Nicholson, Charles Edwards, John Douglas Hopkins; while of his assistants, the names of William Knight, G. H. Stokes, the late George Guillaume, architect, of Southampton, and Thomas Latter, are mentioned. To his credit, Mr. Papworth personally instructed those in his office, and we have heard one of them say that he spared no trouble in explaining designs to his pupils and clerks, who were invariably treated by Mr. Papworth as gentlemen and always welcomed to his house. Mr. Papworth died in 1847,

* John B. Papworth, Architect to the King of Wurtemberg. A brief record of his Life and Works. By WYATT PAPWORTH. London: Privately printed.

at the ripe age of 72. Those who are engaged in tracing the historical growth of modern architecture will find the fragmentary sketches and private papers brought together by Mr. Wyatt Papworth of much value and interest; many of the pages contain Mr. Papworth's own remarks, and, to many architects who remember the period we have referred to, the incidents recorded will have more than a transitory interest.

THE INSTITUTE OF ART.

A NEW exhibition of a very laudable kind has just been opened in the large gallery of 9, Conduit-street, and if we cannot say very much for the first year's collection it must not be inferred that it is not worth a visit. The Institute of Art is apparently a new society which has undertaken the promotion and encouragement, by the aid of prizes and otherwise, of ladies' art work—needlework, painting in oil and water-colours, china painting, modelling, wood-carving, &c., being among the classes of workmanship admitted. Membership is placed upon easy conditions, the only requirement being a subscription to be paid optionally, and that the work exhibited be the handiwork of the respective exhibitors. The right of competing for prizes and certificates is confined to members, though no prize-winner is eligible for more than one prize in the same class, and no member may exhibit free of cost more than four articles. The objects sent for exhibition may be marked with the prices at which they may be sold by the society, and these must include a commission of 10 per cent. for the society, of which 5 per cent. is given to purchasers in the shape of reimbursement coupons. The strength of the present exhibition lies in its needlework, and in this class there are some very creditable evidences of taste and skill—wool-work and crewel-work, lace and embroidery making up a large part of the exhibition. In Class H., "Designs for work," we meet with some pleasing crewel-work, one showing tufts of grass, by "A.M.C." Some designs for curtain embroidery to be worked in appliqué satin and silk is too naturalistic in the design. The Cherwell water-lily table is a pretty conceit, and a Japanese screen is worth notice. The colouring in a few instances is garish, and on the whole it must be confessed the work in this department indicates copyism rather than original design. A tablecloth by Mrs. Dymock is an excellent specimen of decorative needlework. The colours are deep, chocolate and a peacock-green border with white oval-shaped medallions on it. We believe this takes a prize. We note a piece of crewel-work upon blue cloth by Mrs. G. A. Jones, also the figure of a gleaner well-drawn and worked in dark brown by Miss Hope, with considerable care, and a design from nature in crewel marked "E.K." In lace and embroidered work we must not overlook some beautifully-executed Honiton lace flounces by "E.A.," also one by Miss Whitehouse, and some point lace by Miss Parkes and Miss Scott. A child's embroidered robe made in Constantinople at the beginning of this century, and a silk embroidered front of dress, by M. Turnbull, on white satin—the latter wins a prize—claim notice as rich specimens of embroidery. In paintings on fabric we observe a large coverlet with a very confused pattern in which birds and flowers are mixed together in an inextricably confused manner. If we may pass an opinion, the embroidery generally shows a lack of art principle, the patterns in many of the examples are stems and flowers drawn in a too sprawling, aimless manner, and in very few is the attempt made to conventionalise the natural forms. We do not like to criticise the paintings in oil and water-colour; but as first contributions we cannot say much about them. Lady Dunbar, who sends a

few things in needlework, contributes some of the best water-colour sketches. We note two pictures, also "Villa Borghese and St. Peter's," and "Castle of Angelo, Rome," by Miss Riddell; an expressive portrait, side-face, by M. James; "Blackberrying on the Lluger, N. Wales," by Miss J. W. Currey, and a sketch of the Small Canal, Venice, by Miss Lucas. In oils the first prize has been given to a view of a cornfield by Miss S. E. Whitehouse, a lady who also exhibits some exquisite point lace, and M. Currey's "Apple Blossom" also receives a prize. Miss A. K. King's "Shoeing the Bay Mare," after Landseer, is creditable as a laboured copy, "Rocky Pastures," by Alice Green, is more promising, but the "Irish News Boy," by Lady N. Newenham, falls short in drawing. In the painted china a few meritorious works are to be found. For instance, the painted plates signed "K.V.D." has a cleverly-designed group of figures in brown upon a blue ground; another by Miss S. M. Allen is skilful in the arrangement of the peacock's feathers, three of which are placed across the plate, and Mrs. Swain, Brixton, exhibits some very characteristically-painted plates in the Japanese style. The tile painting of Miss Lewis (Doulton and Watts) is vigorous in drawing and colour—a deep red chocolate or maroon being the ground. Miss H. Barlow, a well-known artist, sends a grey and deep blue Doulton vase, in which there is little to find fault with, either in design or colour, and another by the same lady, larger, is also excellent. A vase with blue flowers of a lily type painted on relief must be noticed, and in this department we hope the institute will continue to gain accession of art skill. We cannot mention other exhibits, such as screens, painted and worked fans, carved woodwork, illuminated texts, and old needlework, which fill up the walls and tables, but we congratulate the Council of the Society upon the success of this experiment and the number of works they have brought together, feeling sure that the existence of a society founded upon liberal principles of encouragement will meet with the public support it deserves.

ART APPLIED TO CONSERVATORIES.

IT is a standing reproach against the art of the modern architect that he cannot design a satisfactory conservatory. Very few indeed of the many residences and villas that have been built of late years can show a pleasing connection between the house and this indispensable adjunct. We either see no attempt made to assimilate the two structures, or else the conservatories are designed to resemble Classic temples, mosques, Swiss chalets, and other forms of structure that are supposed to agree with the style of the building. Messrs. T. H. P. Dennis and Company, horticultural builders and engineers, of Mansion House Buildings, E.C., have published Part I. of a catalogue entitled "Art with Economy applied to Conservatories," in which no less than 20 designs for conservatories, with plans, are given, many of them sensible and artistic. In the opening remarks, Messrs. Dennis and Co., observe that they intend to compile in future issues "designs of such originality and merit as will be calculated to secure the approval of the art public, together with the requirements of the profession." The idea of making the construction artistic instead of constructing false ornamentation, is undoubtedly the right one in a conservatory, as in all other buildings, and we confess that in the bulk of the designs in the catalogue of Messrs. Dennis the principle has not been lost sight of. Another equally desirable principle is that a good conservatory should grow out of, and be really an extension of, a reception-room or hall, and this also has been kept in view in all of the

designs. We are glad to see, for instance, in plate 12, the conservatory is shown in a proper relation with the lobby and dining-room. In the next example given, it leads out of the drawing-room, while in a few it is placed in a corner, between the hall and drawing-room, with either or both of which it can be brought into communication by casements. A lobby or fernery may be made a very pleasant means of uniting the two rooms, and we notice some of the sketches show how this may be effected. We believe that it is much better to make this class of structure quite independent of the house in its architectural lines, than that an effort to unite them should be visible when they cannot be agreeably combined without resort to expensive and undesirable expedients. Thus a flat roof disguised by a cornice or pediment is to be avoided if economy is aimed at, and it is far better to connect the room to the conservatory proper by a lobby or short corridor, making the structure itself quite independent in form. We find one or two designs in the book which meet this view of the case; thus Plate 18 shows an octagon plan joined on one of its sides by a short lobby in communication with the drawing-room, and in which lobby an outer door is placed. The octagon is roofed with a lantern. That most awkward of all problems, the design of a Classic conservatory is worked out with much taste in Plate 19; the plan is rectangular and is made to occupy an angle between a drawing-room and study. The roof is flat in pitch and the central span is connected with the building by a small flat roofed side-wing which occurs on each side. By this arrangement the rafters are not cut off on one side against the house and a more architectural connection is made. A considerable variety of ground plan and roof treatment is possible in this way, and an unpleasant effort to unite the buildings avoided. We are glad to find wood is largely used in these structures, and that the mullions, transoms, and sash bars are arranged with some eye to artistic combination and effect. The upper panels of the side lights can be easily made to contribute both to ventilation and ornament, and in some instances, iron frames of ornamental design can be introduced between the piers, or uprights, as we see illustrated in plate 13. The designs are in every conceivable style, Classic, Queen Anne (a style which may be made to lend itself easily to these buildings) Jacobean, Gothic, and Old English, &c. A suggestion is made, which is worth the consideration of those who are about to build a house, and that is, that provision should be made in the plans for the flue of a heating apparatus, a point that, however obvious to the practical builder, often escapes the architect's notice. It may be well to say also that the same apparatus can, if properly devised, be made to heat both the house and conservatory. Messrs. Dennis' tubular boilers are powerful and rapid in their heating, and we understand a combined heating and ventilating apparatus will shortly be introduced by this firm. Several designs for greenhouses, with prices for varying dimensions, are given, which will be found of special use to the profession and the public. Thus we find a span greenhouse made of the best red deal, with rafters 4ft. apart, and the roofs fitted with glazed lights cut, from 2in. thickness, 20ft. long, by 14ft. wide, costs £56 4s. These prices are exclusive of men's time and fixing, painting, brickwork, heating apparatus, and staging. Iron and steel construction is referred to, and a design for a range of conservatories in these materials accompanies the work. A copious list of "clientèle" is appended, from which we find that the endeavour of Messrs. Dennis and Co. to combine art with economy in this class of building has been amply rewarded.

AN AMERICAN OPINION ABOUT THE PRESERVATION OF WOOD.

AN old correspondent has kindly forwarded the following extract from the (Chicago) *North-Western Lumberman*, which will probably interest those readers who have followed the recent controversy on this subject in our columns.

"The subject of wood-preserving, so well understood and so long studied in Europe, has received but little attention in this country (America), owing largely to the great amount of timber so readily obtainable at convenient points, and which has seemed to be an inexhaustible supply. The large drain, however, on our forests, and the oft-repeated necessity of replacing timbers, railroad ties, and planks, every few years, on account of decay, has begun to open the eyes of engineers, architects, and practical men of the country; and in this section, especially, there seems to be a growing interest in the subject, and a disposition to give the process a fair trial. Apparatuses and methods for wood-preserving have been introduced and patented in Europe, beginning as far back as 1700. The most valuable were those discovered in 1832 to 1838, but from careful investigation the Hayford process of creosoting, held under patent here, seems to command as high a rank as any now in use. There are certain objections to the favourite systems now employed in Europe, which this process has overcome. The most important, perhaps, is the fact that it is necessary, in the Bethell process, for instance, that the timber to be treated should be dry, while in the Hayford it can be done better right from the saw, and fully as quick, thereby making a saving of large expenses incurred in sticking and drying. To preserve wood from decay is what is aimed at. There are two kinds of decay—dry rot and wet rot. The former occurs in closely confined localities where there is imperfect ventilation; the latter takes place in wood containing sap and exposure to moisture. To prevent this decay the introduction of creosote oil, filling the pores of the wood, prevents it from absorbing destructive elements, and forms a water-proof and air-tight covering to the wood. The apparatus used is simple and strong; the process practical and easy to understand. A large cylinder 100ft. long, 6ft. in diameter, made of $\frac{1}{2}$ in. boiler iron, is the most important part of the works. A railway track runs through this cylinder, upon which the lumber to be treated is placed, and between the tracks lies a coil of steam pipe, 1,400 feet long, which connects with a boiler. A series of perforated pipes are arranged inside the cylinder for the introduction of the oil; a powerful pump is provided, which, by opening one set of valves, becomes a force pump, and opening another a vacuum pump. The process, to be brief, is divided into two steps: First the wood is placed upon cars and run into the cylinder, which is hermetically closed. The steaming process then commences; the temperature rises to 180 deg. Fahr., and subsequently to 250 deg., which is sufficient to evaporate the sap. By the use of the force pump checking of the wood is prevented. When the sap has turned to vapour, and all portions of the wood have become heated to above 212 deg., the steam is turned off and the vacuum pump set to work; this exhausts all the moisture from the wood to its very heart, and brings it to the second step, namely, the introduction of the oil. The pressure with which the oil is driven into the cylinder is equal to about 70 pounds to the square inch. Every stick is bathed in, and absorbs the hot penetrating fluid. The impregnation is rapid, and in a few hours the doors of the cylinder are opened and the lumber withdrawn. The patents held are not for certain oils as prepared, but 'for improved processes for preparing wood to receive the preservative substance required, and apparatuses for injecting such substance into the pores of the wood thoroughly and rapidly.' The works are in this city, and as the process is becoming more known, the amount of lumber treated will be sure to increase. In a paper read before the American Society of Civil Engineers, in New York, last year, E. R. Andrews, proprietor of the works, made some interesting statements. He mentions, particularly, the importance which this preservation of wood should have in the railroad interests of our country. 'Consider for a moment,' he says, 'the consumption of wood in the one item of railroad ties. Massachusetts, using mostly chestnut ties, which last

on an average six years, consumes in this way annually a volume of lumber nearly equal to the whole product of Maine, and the 80,000 miles of track in the whole country, allowing four years as the average life of ties, actually uses up in ties alone 1,600,000,000ft. annually, or equal to one-sixth of the timber product of the whole country. There are also 76,000 miles of telegraph poles, requiring for their renewal annually 43,620,000ft. of wood, or nearly equal to the products of the State of Maine. Telegraph poles were first creosoted in England 27 years ago, and are as sound as at first to-day. The English Government is now creosoting all the telegraph poles in the United Kingdom. With these facts in view, and the certain value which experience has shown to be true, this subject is placed before us. It is certain that creosoted wood cannot decay; 40 years of accumulated experience proves this. The writer has seen ties which were taken from the Great Northern Railway of England, which have been in wear 22 years, and not a sign of decay is visible. They were actually taken from the road bed to be sent here as specimens. No piles of old rotten ties are to be seen in England lying by the track as in this country. When once laid there they stay. If engineers, contractors, and builders would study this subject more thoroughly, we feel confident it would be found to be true in this, as in other things, "that prevention is better than cure." The Mersey Docks and Harbour Board are now advertising for tenders for 43,300 cubic feet of Baltic red wood sleepers 9ft. by 10in. by 5in. They are to be thoroughly impregnated with creosote by injecting, on Bethell's process, 10lb. of the best creosote oil to each cubic foot of timber."

CONVERSAZIONE OF THE INSTITUTION OF CIVIL ENGINEERS.

ON Monday evening last, Mr. J. F. Bateman, F.R.S.S., President of the Institution of Civil Engineers, invited the members of that society, and a large number of scientific gentlemen to a conversazione in the Engineering Galleries of the South Kensington Museum, which had been lent by the Committee of Council on Education for that purpose. The galleries assumed quite a festive appearance, the corridor entrance was carpeted in red, and decorated with striped material of a similar colour, while the well-stocked galleries devoted to models of machinery and naval architecture were lighted by the electric lights of different patentees. Higgins's incandescent lights, the Electric Lighting Company, Wilde's carbon-holders, Werdermann's lamps, the Serrin lamps, Messrs. Siemens Brothers' lights, and Jablochkoff's electric candles, worked by the Société Générale d'Electricité, were all in operation, the lighting power of the several machines being put to a trying test. Besides the permanent collection of models and apparatus, many new objects of engineering interest were specially exhibited in the galleries, lent by various gentlemen and firms, and the chief difficulty experienced by many of the guests was in distinguishing what were the special exhibits from those of the Museum. Models and instruments of great variety and mechanical interest abounded, many of exceeding ingenuity. To give some idea of the scope of the exhibits, we may name among the numerous models Dr. Airy's continuous self-recording mercurial barometer, and instrument for recording duration of sunshine—of more than ordinary value just now; Mr. G. André's electric mining lamp; a few striking models exhibited by Sir W. G. Armstrong and Co.; model and diagrams illustrating the Thilmer scheme for supplying Manchester with water, shown by the president, Mr. J. F. Bateman, comprising the sections and the lengths of aqueduct in tunnel, cut-and-cover-in, and siphon pipes. Mr. H. Bessemer's specimens of crushed steel cylinders doubtless drew attention; so also the Gramme machines and Serrin lamps in the naval gallery, exhibited by the British Electric Light Company, through Mr. A. F. Blandy, C.E.; Messrs. Clark, Standfield and Co.'s hydraulic appliances for the construction of piers and breakwaters; and Mr. James Dea's model of quay walls on concrete cylinders, Queen's Dock, Glasgow, are certainly ingenious and economic, the latter being of cellular section. Of the few models we had time to glance at, we may refer to Hill and Clark's "Means of hanging and working

railway carriage window sashes." Everyone must have experienced vexation sometimes in trying to raise or lower a carriage window, and Messrs. Hill and Clark's improvement consists in simply allowing the sash to work upon a friction band in the door below, the action of a grip fixed to sash, actuated by a small thumb lever, allowing it to remain open at any point. Hopkinson's steam check or isolating valve, for the protection of connected steam boilers, is a useful but very simple contrivance for preventing accidents and loss of steam. Jordan's rock drill, worked by hand power, will be found useful in mining and quarrying operations, and Mr. H. P. Holt's models of iron and timber trusses, suggestive to the constructive architect. Hot-air engines have been well represented. We note particularly Hayward, Tyler and Co's. Tramways and tramcars are made the subject of improvements. We may name, for instance, Edge's grooveless tramway, a working model of which was shown—the feature being a perforated rail, before described in our pages; Hexwood's spring buffer; Barker's, Kincaid's, and Mackison's rails; B. C. Simpson's tramway brake; H. Vignole's permanent way for tramways, &c.; Holt's starting gear, &c. Of course railway appliances, such as couplings, brakes, &c., were very numerous, so were testing machines, and sanitary inventions. In construction there was a very sparse show of models, the only striking exhibits in this class that we saw being Mr. D. Cunningham's floating swing-bridge, Mr. Buck's drawing of cast-iron rib for underground groining, Mr. Sketcheley's model of wrought-iron viaduct, and Mr. S. R. Stephenson's original design for the Conway bridge, and we must not forget some large diagrams of St. Pancras station roof. Electrical lighting apparatus, incandescent lights, and batteries, had, of course, a large share of attention from the visitors, many of the machines being at work, and we noticed particularly Mr. E. A. Cowper's writing telegraph and electrical automatic apparatus for indicating the height of water in reservoirs, exhibited by the General Post Office and H. Rolfe, C.E.

We may add that engineering science was not displayed in the arrangements of the hat and cloak room; the corridor appropriated to that purpose became choked up with guests unable to relieve themselves of their hats and overcoats, and a delay of at least half an hour arose before any of the earlier visitors could get attended to, the attendants being absurdly few. Among the unusually large assemblage, including the president and the leading members of the institution, were several distinguished representatives in science, literature, art, and diplomacy, not a few of the visitors being architects. The electric light threw a charm over the essentially technical and instructive display of practical science, but one missed the floral adornment of similar gatherings of the sister profession and the presence of the ladies.

SUGGESTIONS OF A STATE RECORD OF THE SURPLUS WATERS FLOWING FROM HIGH AND UNCULTIVATED LANDS.*

BY CHARLES SLAOC, C.E.

FURTHER facilities ought to be given to the sanitary authorities of small towns for combining to obtain the best supply of water within their reach and resources. When the sanitary authority of a small town calls for a report on the best means of procuring a supply of water, the engineer called in finds—or may, and, in fact, often does find—that his instructions are too limited to enable him to propound the best scheme in point of quality, quantity, and economy of working. There are, in numerous instances, several small towns lying near together which have no supply of water, and which have separate sanitary authorities. Moreover, there may be, at no great distance from these small towns, a larger town which requires a further supply of water, or there may be—and, in fact, in one instance at least there are—two such towns.

To confine my remarks to cases within my own knowledge, there are three separate local authorities in a district comprised within a limit of five miles and a breadth of two and a half miles, the aggregate population of which is 25,000. In this district there is no supply of water. At a distance off there are two towns of a population

* Contributed to the recent National Water Supply and Sewage Conference of the Society of Arts.

of 40,000, taken together, and in each town the supply of water is very inadequate, the one in point of quality, and the other of quantity.

Taking first the three smaller towns, each has its sanitary authority, and each has called for a report on the water question, there having been made three reports by different engineers. The instructions to each being limited to the requirements of the one place, the engineer finds it impossible to do more than recommend the best of the sources in the immediate neighbourhood, whereas if any one of the engineers had been consulted jointly by the three Boards, he would probably have recommended a better plan in respect of the three requirements of quality, quantity, and economy of working.

If we now take into consideration the two larger towns also, both of which are seeking means of improving the water supply, but neither of which can do so from the present sources, there appears a further reason for a combination of towns for this purpose.

There is a range of hills, the surplus waters of which would afford an ample supply to all the towns by gravitation. The distance is certainly considerable, but it would probably be found not too great for economy in a combined scheme. But when each authority considers its own scheme singly, it seems preposterous to go to such a distance, and, each authority acting without reference to the others, no one investigates the capabilities of the larger and better source.

What, then, ought to be done in all such cases? It should be, if this Conference thinks well to recommend it, that the utmost capabilities of all such sources to afford a supply of water to towns be investigated and declared. Then each separate sanitary authority would know how much water is within its command, and if, knowing these capabilities, the engineer should advise that it would be economical to make joint works, each authority would add to its share of the cost of the joint works that of its own service reservoir, branch main, and town piping.

An analogous precedent for such a record is the census of the population. When we want to know the population of a place, we do not, individually, count or estimate the number, but turn to the State record. So should it be with water. The capabilities of every area of high ground to afford water for towns should be recorded, both as to quantity and elevation, and all proper sites for storage reservoirs should be investigated, and measured as to their possible contents.

Some of these areas of high ground are already appropriated to existing supplies of water, but many remain unappropriated, either wholly or in part.

THIRTEENTH CENTURY ARCHITECTURE.*

(Continued from p. 582.)

I MIGHT spend the whole evening in explaining to you the various developments of plan which the necessities of the apse and its chevets gave rise to. There is no feature in which so much varied ingenuity has been displayed by the mediæval architect, and to the French (of the Isle de France especially) the palm must be awarded in this matter. None others were so capricious or so bold. The Italians and the Germans never attempted to compete with them, though they constantly made use of the apse, and our own ancestors, as I have said, were led to give it up in favour of the square end, which, though it may be as noble in its effect, is neither so ingenious, nor so difficult in its construction. The whole character of the design of Westminster Abbey is English, not French, and the planning of the apse is unlike that of any French apse, and is distinctly original. In my opinion, it is the work of an architect who, seeing the results achieved by the French architects, desired to achieve the same ends without exactly concerning himself as to the means which they employed; and hence, his work is not only in its detail, but equally in its ground plan, distinctly an English work. The usual difficulty in planning an apse is to get the sides nearly equal, the bays of the aisle regular, and the chapels beyond equal also, and to do all this without waste of space or unnecessary amounts of walling. It may almost be said that no two French chevets were alike, so many were the efforts to produce a

perfect result. In Beauvais, Bourges, Notre Dame Paris, Rouen Cathedral, and Le Mans, you will find the most perfect arrangements—surpassed, however, I am disposed to think, in the work of the French architect of Toledo. You will do well to consult on this point the article "Apside" and "Architecture," in M. Viollet le Duc's "Dictionnaire Raisonné," whose engraved ground plans will explain the ease to you in a way in which no words can. At Westminster Abbey, as I will try to show you on this black-

board, the architect has contrived to make all his chapels exactly equal: but in order to do this he has had to make a rather clumsy mass of masonry at A, between the end of the outer aisle and the first chapel, and he has an awkward bay between the choir aisle and that of the apse, cutting into the perspective. In almost all the French plans the base line of the apse is definitely marked, and the lines, as far as possible, all radiate from the centre of the central apse. At Amiens Cathedral, which is the most perfect, they all do so, as you will see.

The surrounding chapels are all equal, and there is no awkwardness in the junction of the flying buttresses of the apse with the walls and buttresses of the side aisles. In the rough drawing of the eastern end of St. Remi, at Rheims, you will observe a series of 5 circular chapels opening into the processional aisle. At Westminster the line of the commencement of the chevet is not marked; one of the centres of the apse has no chapel opposite, and there is a great awkwardness in the prolongation of the radiating treatment of the buttresses beyond the base of the apse. In this respect no French example is like it. I dwell upon this point so much, in order that I may give you some idea of the nice questions which arise and have to be dealt with in

such constructions, and with the hope that even a slight study of them may increase the interest which you find yourselves able to take in old buildings. Whilst, however, the architect of Westminster was thus, in his own way, solving this difficult problem, St. Mary Overie and the choir of the Temple Church were being built on plans which are more representative of ordinary English work. The Round Church at the Temple does, indeed, stand second to none in its mode of meeting some of the difficulties of vaulting circular buildings. But the choir is an admirable example of delicate English work, and may well be studied, together with the church of St. Mary Overie, or St. Saviour's, Southwark, which is even more interesting. It is a capital example of the skill shown by 13th century architects, who have made a small building look large by the subdivision of the parts in detail. The bays of the choir are only about 12ft. wide, and yet the triforium is an arcade of four divisions. The main columns also may be noticed as extremely good in their design, alternately circular and octagonal, with delicate shafts on the four sides. The eastern chapel, four bays in width by three in length, is still very charming, and though it has been a good deal damaged by repairs, some of the mouldings—e.g., those of the capitals and of the groining ribs—deserve study. You may well notice here also some points in the groining. If you look carefully at it you will see a great difference between the groining of the aisles and Lady Chapel, and that of the choir. In the former, the diagonal rib is a semicircle—in the latter it is a pointed arch. The former by much more agreeable, for the eye is carried forward from one rib to the next, without a violent pause, and thus is in every way better in effect. Uffingham, in

Berkshire, is one of our best 13th Century churches, and this had an octagonal central tower, and a chancel with its eastern bay alone groined. Hythe, in Kent, is far finer; here the clustered shafts, the elevation of the chancel above the nave, and the contrast between the simplicity of the nave and the magnificence of the chancel, and the beauty of all the detail make it one of our most perfect examples of a parish church on a small scale. Here the whole eastern part was groined. Stone Church, near Dartford (which you ought to visit), is specially interesting, because there can hardly be a shadow of doubt that it was built by the same architect as Westminster; but it has a square east end, and it was my happiness some years ago to restore the vaulted roof of the chancel, which had two bays of plain quadripartite vaulting, and a square east end. Here, as at Hythe, the whole of the details are most delicate. I shall not detain you longer on questions of ground-plans, but I repeat, that you ought, when you visit an old building, first of all, to notice its peculiarities in this respect. You will find certain arrangements of the plan contrived to serve certain recognised wants, and the way in which these have been modified as fresh wants arose, so as to meet the requirements of special rites, is among the most interesting subjects of inquiry to the ecclesiologist. Each nation had its own special development in consequence. In Germany and France and Spain, almost all buildings had stone vaults, and the architect had, therefore, to take his heavy roof into account from the commencement. In England, on the contrary, stone roofs were uncommon, save in our grander churches, and the architects were, consequently, much less bound to make their plans regular and symmetrical, and an amount of variety was a consequence of this, for which we may well be grateful.

* A Paper read by GEORGE EDWARD STREET, R.A., before the members of St. Paul's Ecclesiological Society, May 21st, 1879.

The next point to be observed is the general character of the design. Now this depended in the 13th century, just as much as it does now, on the taste and skill of the master mason or architect, and you will find all the difference in the world between the work of one man and of another. They were affected also by the material available. If you find yourselves in Sussex, visit such a church as Clymington, and you will see how the architect contrived, with very humble materials, and very small amount of enrichment, to produce a work of art almost as interesting as the sumptuous works which at the same time were being built in the far richer districts of Northamptonshire and Lincolnshire. His work had few mouldings, and seldom went beyond the use of a delicate chamfer for all angles. This use of the chamfer is one of the features of the period, and it is singular how much may be done with it. In this work the windows are simple lancets with deep splay; the glass is set close to the outside face of the wall, the buttresses are simply weathered, the roofs are of timber arched in a simple fashion, and the towers so simple in design that you might almost suppose no architectural skill was required, for they are finished with simple pieces of oak covered with shingle. Yet they are not inferior in artistic character, or in the proper use of material, to the Northamptonshire stone churches, where the architects having good stone close at hand, and the example of their cathedral architects to guide them, built churches full of precious and beautiful detail, designed a number of varied towers and finished them with stone spires, which are to the present day the proper subject of admiration to all of us. But to understand how to observe these very varying beauties, you must know how to observe and distinguish the features of detail which give them in an architect's eyes so much of their value.

And first, as to mouldings. You know the office which they fulfil doubtless, but without study you cannot understand how subtle their beauties are, and how much the effect of the finest works depends upon their being well designed, or the contrary. The chamfer was the great improvement introduced by the 13th-century architects. It was formed by cutting away the angle thus (Mr. Street proceeded to trace on the blackboard the progress of the changes that could be effected on a stone by cutting mouldings upon it, as shown on accompanying illustration); the next step was to hollow the flat surface so as to afford a play of light and shade upon it; or the angle might be left, and the parts of the stone above and below each cut into by a roll, or into two half-rolls; then the hollow was deepened, and a small fillet added beneath it, and these rolls and fillets were multiplied so as to vary the effect of the shadows and lights. The string-courses, plinths, and bases were similarly the subjects of similar changes, all made with the object of getting more variety of light and shade, and so as to enrich and emphasise the architectural lines. Nowadays mouldings are too often drawn without the slightest sense of their fitness for the place, but these 13th-century English mouldings were, I think, the very best in Europe; they were well-drawn, fitted to their places, and infinitely varied in section. They were adorned with dog-tooth and other carving. They cannot be understood without reference to a point in which there is as much difference between English and foreign work as there is in their plans. This is the shape of the abacus of the capital. Amongst the French the use of a square abacus led to a square section of mouldings, and to great uniformity in their design, but they secured one fine effect of shadow—breadth and boldness. In England by the end of the 12th century the square cap was discarded in favour of a circular one, and with results not foreseen. It was impossible to plan mouldings with a broad plain soffit. It became necessary instead to plan them on the chamfer plane, as mouldings fitted to squares would overhang the caps. So it was necessary to devise fresh forms. Then there was a loss of light and shade so simply obtained by the old fashion, and this was regained very skillfully by deep-cut hollows at the junctions of stones, and among the mouldings. To our circular cap we owe our beautiful system of mouldings. This necessity for the study of effect by means of moulding led to the use of mouldings to an extent undreamt of by other schools. Our English capitals, instead of being always carved with foliage,

were more often moulded. With moulding the architect knows exactly the effect he will produce; with sculpture, unless he models all his work himself, he is at the mercy of some one else for a most important feature. Wherever you go, let me beg you, therefore, to make a point of examining mouldings with the greatest care. Whenever you have come to understand them, you will find your power of distinguishing between good and bad works, whether old or new, wonderfully increased, and the pleasure you can take in good work increased in proportion. One note I must make here, which is, that the rounded and soft lines of 13th century mouldings accord singularly well with the round and true lines of traceries, with the circular shafts which were so much esteemed, and, indeed, with all the features of the buildings they adorned. So much is this the case that when at the end of the century the window traceries became more complicated, and the columns ceased to be shafts or clusters of shafts, the mouldings were all altered to harmonise with them, and in the 15th century the hard, sharp lines of mouldings tallied exactly with the formal and precise designs of the traceries. The columns of the 13th century were circular, octagonal, clustered, grouped in fours with smaller shafts at the angles, or even with double series of the attached shafts, to give great richness of effect. Their variety was endless. Indoors they retain the general arrangement of the 12th century, a series of columns in square recesses, one with angles taken off or moulded. For detached purposes they are of the various sections sketched (see below), and in this age it

of five and even of seven—then contained under an arch, then adorned with cusped or plain piercings in the wall above, then combined with circles; cusplings grew before the end of the century into most elaborate traceries, but very early in the century, as at Netley Abbey, had produced distinct tracery, and by the middle of it in the Chapter Houses at Westminster and Salisbury, we see traceries of the most complete and finished description. The Westminster Chapter House windows were finished in A.D. 1253. Essentials of good tracery are subordination of members, and divisions into primary, secondary, and tertiary orders of tracery. These are carefully observed in work of the 13th century. At that time the design of openings was as important as the lines between them, so that whether you regard the lines of stonework or the voids, the eye is equally gratified. Differences between early and late traceries are all in favour of the former. The arrangement of cusps is well worthy of attention. Ogee lines are never used, the cusps are inserted in a groove, and the cusping of arcades is undercut, as at Westminster. Very frequently its outlines follow no stiff mathematical lines, but show by their variety and freedom that they are drawn by hand, as at Lincoln. In the earliest cusping all the mouldings follow the cusps; the later cusps are subordinate to an inclosing line. When you visit Westminster Abbey, ask permission to go up into the triforium, where you will be able to judge of the rich effect of the double traceries, partly moulded, partly carved, and very plain on side next roofs, but still good. The arcades at Westminster and Stone are, by

became the fashion to form these columns of marble. This could not be got in long blocks; hence came banded shafts. The extent to which this charming custom was carried may be seen at Westminster, at Salisbury, and the Temple Church. It had its inconveniences, however, in construction, as these collections of columns depended on their caps, bands, and bases for holding them together, and, therefore, for their strength; and it was found, before the end of the century, that safer building could be done with stones built in courses, and so gradually marble shafts went out of fashion. But they are one of the special and most beautiful features of the 13th century.

In the windows, doorways, and arcades of this century we may again trace primarily the same sort of development from the rude original. The lancet was doubled, trebled, arranged in groups

the way, identical, but have been horribly defaced at Westminster. The heads of windows of this period were moulded, carried on shafts, and generally struck from a centre lower and different from the exterior arch. The doorways of the 13th century are among the best features. The large doors are often double, as at Lincoln and Ely, and are generally under an inclosing arch. The jambs are a series of shafts, engaged or detached, and in the latter case have bands. In small doors the heads are trefoil or segmented. One of the features which most strike us in these is the hammered iron-work of the hinges. This was very varied in pattern, delicately beaten out, a work of love to the workman, and so well and artistically executed that it is difficult to get anybody to do anything like it in spirit now. English doors, however, are not so fine as French; those, for

instance, in the west front of Salisbury Cathedral are mere holes in the wall, and as a rule our doorways are low and small. The porches, however, are very fine, as at Wells and Salisbury, groined with arched at the sides, sometimes with fine outside arches, and generally in such cases of two stages in height. The carpentry of this period was certainly not so good as the masonry, and this was very clearly the case in the roofs. These are of oak, and the rafters are pinned together with king-posts. These often resemble 15th century work; but look carefully at the sections of the tiebeams and the king-posts, at their mouldings and outline, before assigning a date. Arelid timbers were used, but not so commonly. In the steeples the custom of the district affects the design very much. There is a great change herein from the work of the 12th century. Instead of being large and clumsy, they were, as a rule, lofty in their proportions, and surmounted by spires. Many examples are either octagonal or partly so. Stone spires of this date as a rule have no parapets. They just overhang the walls of the tower, which finish with an eaves cornice under them. These eaves cornices are a feature of the style. The tower buttresses usually finish below the belfry, and this is richly areaded with columns to its windows, and at the angles. The spires have spiral lights, but always on the cardinal sides, and not on the angle sides. So, also, buttresses are always square, and never diagonal, as in the Perpendicular period. The spiral lights have shafts for monials. Pinnacles are not so common as afterwards, but they do occur, generally rising out of the branches of the broach spire. You will often find that the 13th century belfry stage was not considered fine enough or lofty enough, and has been surmounted by another at a later period, as you may see at Oakham and Grantham. I think we owe our best spires to Normandy, where, at a very early date, very fine examples were erected, as at Caen. Some admirable examples remain, as at West Walton, in Norfolk, which are covered with arched, have octagonal angle pinnacles, from the ground up, finishing at the top in a timber spire, covered with lead. The spire is gone here, but at Sutton St. Mary, on a nearly similar steeple, it remains. Both are detached towers. You may see a good copy of that at West Walton at a church in the City-road, designed by Sir Gilbert Scott.

Sculpture is of two kinds—1, foliage; 2, figures. That of foliage shows a great development on what had gone before. The best Transitional caps were copied from Corinthian, and in French work natural foliage was to some extent grafted on this. Early English foliage is marked by its extreme gracefulness. The same sense of beauty which made the architect's design so graceful naturally produced this result. The idea was, as a rule, not to copy natural foliage, but to give a conventionalised representation of the essential facts of nature. The variety is great, but the commonest form gives us either capitals with distinct but regularly-arranged masses of foliage, each of these being a branch of foliage, growing firmly and very gracefully from the neck of the shaft. Or another variety gives caps with a continuous mass of foliage. In addition to this necessary carving on old lines other occasions for its use were devised. One of the most characteristic is the custom of diapering the plain surface of a wall, as at Westminster Abbey. The delicacy of these diapers is extreme; see, for instance, some in the Chapter House at Westminster. Another use is the carved decoration of mouldings; sometimes with foliage, oftener with the dog-tooth. This was for giving emphasis to a moulding, and was a development from the nail-head, which was also still used. Foliage was also used for stopping mouldings under caps, for covering a transition from circular to square of the base, and for the ends of cusps. Towards the latter half of this century the custom of copying natural foliage was much adopted, as at Southwell Minster. This was beautifully executed, and under certain conditions may be allowed; but it is inferior in excellence and in skillfulness to conventionalised work. The leafage is always very luxuriant, growing in very strong curves with extremely good light and shade, and often undercut in the most elaborate manner. The leaves generally exhibit some variety of trefoil; no architectural foliage is so good as this usually was. You ought to carefully notice the spandrels of the arcades at Westminster and

Stone, and the leafage round the arch mouldings. Sculpture of the higher sort, of figures and subjects, was not so common in England as in France. The west front of Wells is the finest example we possess. But you may look at Westminster at the angle in the spandrels of the transepts, and at the bronze figures of Henry III. and Queen Eleanor on their monuments. These are thoroughly fine works of art; they were executed by Torel—an Englishman—and in a style which makes one proud of him even if his work be compared with the best of the contemporary Italian artists, such as the Pisani. The best sculpture is generally that of recumbent effigies on monuments. At Ilgham Ferrars you will see panels of sculpture in the fine west doorway, and the South Kensington Museum and the Architectural Museum afford you more opportunity of studying this art than most of our old buildings, so complete has been the destruction of figure sculpture in our churches, thanks to Puritanical fanaticism. Draperies always hung in straight and simple folds; the figures are always draped, generally picturesquely posed, and subjects very simple in their story, and not at all complicated in their treatment.

The decorative work of this age is to be studied as well in this city as anywhere. Not to speak of what you may see in museums, consider what you have at Westminster. To begin with, there are the pavements of Edward the Confessor's Chapel and before the altar. They are of opus Alexandrinum; the latter was given to the church by Abbot Ware, and finished in 1268. It is similar in style to the pavements in many Italian churches, and an admirable example. You should examine this altar pavement carefully, and note the difference between it and that in the Confessor Chapel, which is probably an English imitation. Of the same period are the encaustic tiles in the Chapter House—some of the best in England in execution, though not the most fitting in design. They represent traceried windows, intersecting squares and circles, and very elaborate foliage. Then, again, there is the shrine of the Confessor, another work, like the pavement, of Italian origin; the wooden sedilia and the Coronation chair, the enamelled figure of William de Valance, the painted altar frontal or retablaux, the ironwork in front of Queen Eleanor's tomb, are all of them works of the 13th century, by a careful examination of which you may arrive at some sort of an idea of how a church well furnished throughout at that period looked.

Now as to stained glass. In the 12th century glass was almost always of one description—a mosaic of rich colour. In the 13th century, though to some extent the mode of design was similar, the details were more elegant, and the use of white glass was developed. The principles on which it was designed were simple and true. Pot metal was used for colour, stain being seldom used until the end of the century. You should notice the drawing and the arrangement of subjects in panels with grisaille between. Leading followed leading lines, and the ironwork followed the general scheme, and added much to its effect. The only shading was a thin smear, which being removed left transparent glass for the high lights. The drawing of details of stained-glass was extremely bold and careful; generally it was strongly outlined, and leaves were filled in with delicate lines instead of shading. This is entirely correct in principle, and although I have not a word to say against later glass, I always feel on looking at that of the 13th century that none surpasses it in brilliancy and force of colouring. The design was also never a mere imitation of stonework, but always a genuine design made for glass and suitable for nothing else. The introduction of grisaille was one of the beauties of this style. Note also how the ironwork of the windows was designed to harmonise with the glass; and in some cases it was almost as beautiful.

It is time to conclude. I have tried to show you that the art of which I have been speaking was not only true, and good, and consistent in all its branches, as all living and real art must be, but that it had transcendent merits which can only be thoroughly appreciated by those who have really made a study of them. To me a beautifully drawn moulding is a source of the greatest pleasure, and I never see a moulding which produces such good effects as do those of the 13th century. The hands which fashioned them were indeed those of cunning artists,

trained in the best way. Yet they did not despise formal systems of perfection, for at this time more than ever buildings were undoubtedly often planned on some geometrical system of proportion, of which the equilateral triangle was usually the foundation. This was certainly the case in the noble Abbey of Westminster, of which I have had so often to speak to you. I have not been able to tell you a tithe of what I should have liked to say. I ought to have been able to tell you not only of Westminster, but of countless other churches, large and small, throughout the land, all worthy of study. I could have told how they may be classified into groups, speaking to us of the skill and genius of individual architects, each in his own district or diocese; or I might have dwelt on the vast development of monastic architecture in this century, and how in some districts—as Yorkshire—the ruined abbey afford evidence of the existence among us of architects second to none in Europe of any age. I might, too, have told you that this art was not confined to the church, but that everywhere and for all purposes, it was one and the same in spirit and in intention. Indeed in those days art was the natural expression of men's delight in their work; and we need not be surprised if we find it marked more than that of almost any other period by all the characteristics of the best art—simplicity, grace, tenderness, sobriety, purity and force, are the virtues it possessed! Few, save those who have given their lives and all their enthusiasm to the study, know how completely all these terms are justified, or understand how each inspection of a work of this great age, each study of it in detail, increases one's respect and veneration for it. We know next to nothing of the men who wrought these marvels. They worked for God and their church, in the best way and with little thought of themselves. We have the greatest difficulty in imagining to ourselves how the result was attained. Every workman seemed to have been an artist, and to have known how he ought to work. Yet there were no museums, no schools of art, no lecturers on art. They had undoubtedly a public who understood and encouraged their work, and here they had an untold advantage over us at the present day. We have a public which is swayed in every direction by every breath of popularity and fashion, a public which admires good work and bad work with equal zeal, and which seldom troubles itself to know whether it has any reason for admiring, or indeed whether it is possible that there can be creeds of right and wrong in art, which make some things admirable, and others fit only for condemnation. It is because such a society as yours may lead some men to study in an intelligent way these noble works of the highest period of English art that I have responded readily to the request that has been made to me to speak to you this evening; and though I cannot hope to have given you much information on a subject which is far too large for such a lecture, I trust I may feel that I have persuaded some among you that there is enough merit in the remaining works of the 13th century English architects to make it worth your while to devote yourselves to some further study of them in detail beyond what you have ever yet devoted to them. If this be so, I shall not have lectured entirely in vain.

PICTURES BY M. GUSTAVE DORÉ.

TWO additional pictures of colossal dimensions, by M. Gustave Doré, have just been added to the Doré Gallery in New Bond-street, and through the courtesy of Messrs. Fairless and Belforth, the proprietors, we have taken the opportunity of a private view to inspect these latest works of that artist. One is a picture of the "Ascension," and after M. Doré's "Triumph of Christianity," we consider it to be among his finest compositions. The "Ascension" has been a theme upon which the greatest painters of all ages have delighted to exercise their power of imagination, and so far, indeed, the materials and conceptions of the Italian masters have been ready to his hand; but notwithstanding this qualification and whatever technical faults we may find in M. Doré's painting, it will be acknowledged that he can invest the figure of Our Saviour with ideal grandeur and dignity worthy of the subject and the scale adopted. In the painting before us the central figure of the Saviour realises the attributes we look for. He is shown ascending through the cloud, robed in light blue

drapery, with extended arms, the lower portion of the picture being filled with a crowd of ministering angels, while above the Saviour's head a glory of angels rise in perspective gradation. Through a drifting cloud in the background are seen the small and distant group of his apostles looking steadfastly towards their Lord. The life-size figures that crowd the canvas, and the whole composition is symbolic in treatment, well balanced, and impressive in outline and accessories. The left-hand angel is perhaps chargeable with being rather stiff in drawing. In the colouring the artist has chosen light and harmonious shades; the effulgence of the "glory" above the head of the Saviour seems to irradiate the group below, and there is an opaline hue in the tints and blue of the drapery that throws a splendour over the whole picture. In the "Ecce Homo," M. Doré has shown Christ crowned with thorns, clad in the scarlet robe, descending a flight of steps. On each side of him are Pilate's soldiers, while below is a surging mob of Jewish rabble, in various attitudes, mocking and gesticulating. The composition is simple and symmetric; the hall of judgment forms the background of the Saviour's figure, which seems to stand out in marvellous perspective. The groups of figures are painted with the same dramatic power and action that strike us in most of this artist's work, and the picture must be pronounced a success. Unlike the "Ascension," the colours selected are deeper, and the handling more solid and massive, befitting the subject chosen. Those who admire grand, imaginative compositions of this class will find in M. Doré's two recent additions to the gallery further evidence of this master's power of conception and boldness of execution, that places his works almost beside the masterpieces of Correggio and Michael Angelo.

LIVERPOOL ENGINEERING SOCIETY.

THIS Society held its usual monthly meeting on Wednesday week at the Royal Institution, Colquitt-street, Mr. Morgan E. Yeatman, M.A., in the chair.

A report was read by Mr. Coard S. Pane, Assoc. Inst. C.E., on the means of communication between Liverpool and the Cheshire side of the Mersey, past, present, and proposed. The paper was illustrated with plans, diagrams, and views of Liverpool at the various dates referred to in the paper. The author commenced by giving a sketch of the early history of Liverpool in connection with the ferries, and remarked that with one exception he had been unable to ascertain the date of the establishment of the older ferries, and he concluded therefore that originally they had only been simply convenient points of access, to which persons were ferried who had business at the various places on the opposite side of the river, and as time advanced steps were constructed, and the regular ferries grew into existence. A drawing of Liverpool in 1728 was exhibited, showing the landing-stage near the present Custom House, and old ferry-boats, called "grabs," which used to ply before steam was used. Particulars were given of the cost of the various new piers and stages which in latter years have been erected; a description of the old *Elva*, the first steam ferry-boat run on the Mersey, was given. The various alterations in the fares were given, from the time when the monks charged a farthing to the present time when a penny is charged. The author entered fully into the various improvements in the mode of embarking and disembarking on the Liverpool and Cheshire sides, commencing from the period when passengers walked out to the "grabs" on planks and tressels to the present date, when they pass comfortably on to the boat by means of the magnificent landing-stage and Mr. Harkness's ingenious gangway. Attention was then drawn to the various schemes which have been proposed for crossing the river by bridges or tunnels, and sections of the river at the various points of crossing were exhibited. In concluding, the author hoped that the energy which had enabled the promoters to carry out the railway between Liverpool and Manchester in 1829 had not died out from amongst us, and that some means of connecting parts of Liverpool and Birkenhead would be effected.

An interesting discussion then took place, followed by a vote of thanks to the author.

Mr. Westley has been appointed surveyor to the Local Board of Leyland, near Preston.

COMPETITIONS.

BIRMINGHAM.—We understand that more than fifty designs have been sent in in competition for the new Wesleyan college about to be built at Birmingham, at a cost of about £25,000. Mr. Alfred Waterhouse, A.R.A., is to be the professional referee.

RAMSGATE PROPOSED NEW ROAD COMPETITION.—At the meeting of the Commissioners on Tuesday week a strong effort was made, after a surreptitious canvass of the town, to push forward the claims of the design "Viator No. 2" and two other designs, which are practically out of the running. The first-named design is said to be by Mr. Pite, a member of the Board. The attempt alluded to was, however, a total failure; the recommendation of the sub-committee was rejected, and it was resolved that the following eight designs should be reserved for further consideration, viz.:—"Front," "Che Sara Sara," "Economist," "Westminster," "Advance," "Percy Britton," "Viator No. 2," and "Audsoter et Sincere." Mr. Abernethy was requested to favour the committee with his notes upon these designs made during his inspection. It would thus seem that the premiated designs are altogether ignored—a somewhat remarkable circumstance. Some of the inhabitants of Ramsgate openly state that the whole scheme will fall through. It is to be hoped this will not be the case. The Commissioners have, at least, two good designs before them, and if they could be induced to call in an independent and competent professional adviser, and disregard the opposition of the tradesmen of Harbour-street, who are strong on the Board, and are mistakenly opposed to any design which does not cross Harbour-street on the level, a satisfactory result might soon be arrived at.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

BRITISH ARCHÆOLOGICAL ASSOCIATION.—The eleventh meeting of the Session was held last Wednesday; Mr. Syer Cuming, F.S.A. (Scot.) in the chair. Some charming paintings copied from the roof screen of Westall Church, Suffolk, were exhibited by Mr. Watling. This screen has a remarkable series of figures of apostles and saints, each with his proper emblem, and of 15th Century work. Mr. Cecil Brent, F.S.A., exhibited a small cylinder of Assyrian date, the inscription upon which was rendered by Mr. de Grey Birch, F.R.S.L. Mr. Morgan, F.S.A., described a Spanish figure of the Virgin Mary, which is said by tradition to have been carried by the Christians before their armies during the Moorish wars. It is about 18in. in height, and is admirably carved. Mr. Loftus Brock, F.S.A., described a series of fragments of Samian ware recently found in excavations near the Bank. They are for the most part ornamented, and are remarkable for showing traces of some great fire in remote times, many being burned black, a peculiarity which has frequently been met with in other parts of London. The first paper was by Mr. W. G. Fretton, F.S.A., on the antiquarian losses in Coventry during the last 150 years. The history and position of all the ancient buildings of the City which have been demolished during that period were passed in review, and the circumstances of their removal were dwelt upon. Their demolition was occasioned for the most part by the indifference of their custodians, who appear to have had no interest in them as examples of art. A similar record might be made of almost every other ancient town in the country. The loss of the beautiful market-cross, and of the town gates, was especially dwelt upon. The restoration of the churches has resulted in several ancient features being brought to light, but much unnecessary "newness" has been given to these buildings. In the discussion which followed, the principle of removing the work of the last 200 years, in so-called restoration, was condemned by several speakers. These were evidences of the history of the buildings, as well as the features of older date, and should be retained. The second paper was by Mr. Pinches, who described the remarkable bronze gates recently brought to light by Mr. Rassau, at Belewart, nine miles from Nîmroud. The circumstances of the discovery, the position, and the whole series of the figures on the bronze plates, were passed in review in an exhaustive manner, and were illustrated by several admirable

photographs. The so-called Greek figures were referred to, and the peculiarities of the armour pointed out.

PARLIAMENTARY NOTES.

METROPOLITAN FIRES.—Last week, in the House of Lords, Lord Granville, in a comprehensive speech, brought under notice the provisions made in the metropolis for the extinguishing of fires. With the view of placing the case clearly before the House he directed particular attention to the report of the Select Committee of the House of Commons which sat in 1877. He gave the highest praise to the Fire Brigade; but pointed out that they were too few in number. The circumstances on which, however, he particularly relied was the want of unity in the forces which ought to be brought to bear in case of fire. The police were not in any way combined with the brigade, and though as a rule the breaking-out of a fire was discovered by a policeman, his exertions in the matter were confined to giving the alarm. Then when the brigade arrived it was powerless till the turncock appeared upon the scene; and the turncocks of London were in the employment of eight water companies. The noble lord strongly advocated a unity of action between the police, the brigade, and those who had the control of the waterpipes. To bring this about he regarded an amalgamation of the eight water companies under one single central authority as indispensable. He concluded by moving for papers. Lord Beauchamp, in explaining that the Government did not see their way to taking action in the matter, though they admitted it to be one of great importance, said the nearer they approached the subject the more evident became the difficulty of dealing with it. Lord Aberdare regarded the reply of the Government as a disappointing one. The subject brought under the notice of the House by Lord Granville called for speedy legislation. Lord Denman said that legislation on the subject in the present Session was impossible, but every house ought to be provided with a steam apparatus for extinguishing fire. It could be procured at a trifling expense. Lord Shaftesbury observed that 30 years ago he was chairman of a Board of Health which proposed a scheme for a proper supply of water to the metropolis. The result was that all the water companies rose in arms and an end was put to the Board. The supply of water was so shameful in some parts of London that if a conflagration broke out in one of them another "Fire of London" might be looked for. The health, safety, morality, and happiness of the people of the metropolis demanded immediate action in this matter. Lord Fortescue also urged the necessity of immediate action. The Duke of Richmond and Gordon thought that some of the noble lords who had spoken on this subject were unreasonable. They did not appreciate the difficulty of the question. He knew it had engaged the attention of the Home Secretary, and that his right hon. friend would be the first to introduce a measure for dealing with it if he could only see his way to doing so. Lord Camperdown told the Government that they had that evening given but cool comfort to the inhabitants of the metropolis. The motion for the papers was then agreed to.

CHIPS.

A petition has been filed in the Bradford bankruptcy court, on behalf of James Lumley, civil engineer, of Kirkgate, Bradford, and engineer to the Altofts local board. The liabilities are estimated at £36,000. Mr. Lumley has been compelled to adopt this course, it is stated, in consequence of the heavy demands made upon him by building clubs with which he is connected.

Mr. Cross took part on Saturday in the opening of the second block of artisans' dwellings at Stroud-Vale, Islington, and subsequently laid the foundation-stone of a third block, to be erected with a like object, by the Victoria Dwellings Association. Mr. Charles Barry is the architect.

A new infirmary is about to be erected by the guardians of the Croydon Union for 600 beds. The Pavilion principle is to be adopted. The site covers an area of about eight acres. Plans are being prepared by Messrs. Berney and Monday, architects, Croydon.

Improvements are being carried out at the Congregational chapel, Burnham, Essex, including the erection of a spacious gallery. The work is being done by Mr. Charles Read, of Burnham.

ILLUSTRATIONS.

CHURCH OF ST. MARY, SPEENHAMLAND.—NEW TOWN HALL, LOFTUS-IN-CLEVELAND.—DETAILS FROM ST. GEORGE'S CATHEDRAL, SOUTHWARK.—PREMIATED DESIGN FOR COTTAGE VILLA.—EXAMPLES OF WROUGHT IRON WORK.

OUR LITHOGRAPHIC ILLUSTRATIONS.

ST. MARY'S CHURCH, SPEENHAMLAND.

ST. MARY'S Church at Speenhamland, Newbury, was built about forty years ago in poor style. The entrance front has been taken down and a new chancel, chancel aisle, organ-chamber, and vestry erected in its place, and new columns and arches are intended to be erected in the nave with roofs throughout. Mr. G. E. Street, R.A., is the architect under whose direction the alterations and additions are being made.

TOWN HALL, LOFTUS-IN-CLEVELAND.

THE Earl of Zetland has acted the part of a liberal proprietor towards this small town. For many years the magistrates had experienced great difficulty in conducting public business, owing to the absence of any room or hall suitable for the purpose. With the advice of his general agent, Mr. George Dale Trotter, his lordship accordingly resolved, not only to meet the want in question, but to erect such a building as should be generally serviceable for the inhabitants. The result is, the new town hall, erected in a freely treated style of Late Gothic, from the designs of Mr. E. R. Robson, of Parliament-street, London. On the ground floor the building comprises police-court, local board room, clerks' office and retiring-room. On the first floor there is a public room, news-room, office and ante-room. The site, which adjoins the parish church and has a frontage to the main street of Loftus, as well as the building stone from the local quarry, have been presented by Lord Zetland. In addition thereto, he has defrayed the entire cost of the building, which, with other expenses, will amount to about £4,500. A clock will be placed in the tower as a memorial to the late Lord Zetland, the cost amounting to £200, being subscribed for by the tenants and others connected with the Upleatham and Loftus estates. The contractor is Mr. Thomas Dickinson, of Salisbury, and the clerk of works Mr. James Patterson. The original drawing from which our lithograph has been taken is now on view at the Royal Academy.

ST. GEORGE'S CATHEDRAL, SOUTHWARK.

WE publish a few details from the above church, consisting of a drawing of the brass gratings over the hot-air chambers, and a niche for the statue of the "Sacred Heart." The conditions were that the gratings were to be emblematical in design, and that both should be in harmony with the structure, the work of the elder Pugin. These additions were designed by Mr. Herbert A. Gribble, and executed by Messrs. Farmer and Brindley, of Westminster Bridge-road.

PREMIATED DESIGN FOR COTTAGE VILLA.

WE this week give an illustration of the successful design of cottage villa by Mr. H. E. Clifford, architect, Glasgow, for the Utilities Land Company, Limited. The villa is designed with the view of producing at limited cost a more picturesque character than is usually attained in small houses that are square in plan. The building occupies an area of 33ft. by 27ft., exclusive of projections. The ground floor contains two sitting-rooms, kitchen, and scullery, with other conveniences. The upper floor, the greater part of which is in the roof, contains four bedrooms, bathroom, and napery closet, the ceilings being respectively 10 and 9 feet high. The external walls would be built of brick with stone dressings. The interior finishings of yellow pine stained and varnished. The upper portion of transomed windows glazed with quarry glass. The roofs to be covered with green slates with tiled ridges.

LATE WROUGHT-IRON WORK.

THESE examples from Chelsea and South Kensington Museum have been chosen by Mr. Penstone from his sketch-book as among the best to illustrate the points of design and construction remarked upon in his lecture read before the Architectural Association on Friday last, and reported on pages 613-6 of our present issue. The fanlight from South Kensington Museum is a fine specimen of 16th Century German work, and the details given clearly illustrate the example. The bits from Cheyne Walk, with the perspective of the gate at No. 16 of the same street, show more familiar work, though probably none the less valuable and suggestive. The German court-yard bell of 17th Century date is exceptionally interesting.

THE IDEA IN PAINTING.

LAST week the members of the Manchester Academy of Fine Arts and of the Manchester Literary Club, with other invited guests, assembled at the Royal Institution, Manchester, to hear a lecture from Mr. Ford Madox Brown on "The Idea in Painting." Mr. Madox Brown, after excepting pre-historic art from his remarks, said that painting was originally representative, but as it developed the love of it as imitation of nature increased, and the modern practice of complete imitation was consequently the natural outcome of the earlier, but the earlier contained the essence of the art. The idea in it, therefore, now claimed investigation. If in the twenty-five years between 1850 and 1875 we could boast of some progress in the material side of painting, it was to the quarter of a century preceding it—the epoch of MacIose, Wilkie, and Leslie, of Delaroche, De la Croix, and Ingres, of Cornelius, Overbeck, and Kaulbach—that we owed the modern vigorous development of the idea as subject matter in painting. Since 1850, indeed, there has been a positive reaction. Epochs had their inevitable duties and channels of progress, and it might be necessary that now lines and poses of delicate tints and the study of what was beautiful *per se* should engross us, but in aspiring to fresh conquests we should be careful not to let slip those we hold already, and against this our voices should be raised. The painters without ideas at all times outnumbered those who had them. It was ever by a struggle that the rarer quality of thought—which was poetry in painting—was kept to the front. There was ever a powerful party among painters who, being without thought or poetry themselves, tried to persuade others that mere imitative painting, with no idea, or only such trite ideas as could be picked up in shop window, was the proper and desirable kind of art. According to this section every subject that represented more than a figure or two, with a snatch of background taken direct off nature, was amenable to the charge of "literary ideas." M. Courbet was chiefly responsible for this school

in France, and pulled down the Vendome Column probably more in hatred of the art which adorned it than of the system it commemorated. It was an idea itself, and it was covered over with ideas, and Courbet honestly hated ideas, for he could not understand them. He was a highly endowed painter and a fine colourist, and that which he could paint best—a study from nature—he wished every one to accept as the only legitimate art. Hence, it would appear sprang up, the impressionists, a school of painters not only confining themselves strictly to what they found ready composed for them in nature, but undertaking to convey only the first impression of it, with the bloom still on it, resulting, as we might imagine, with the clever ones in clever sketches, and in some rather peculiar "splotchings" of colour with the less gifted ones. Any school of art that leaned stoutly on nature must in the end accomplish good, but there was some work left before we consented to abandon ideas which held away in the Greek Pantheon of sculpture, in the Christian art of Giotto, in the renaissance glories of Buonarroti and Raffaele, and of Durer and Rubens and Hogarth. The idea in art began precisely where the literary idea left off, and that which one art was best calculated to express the other was the worst at conveying. Mr. Brown, after saying that art ideas, like other ideas, were not all of the same calibre, proceeded to describe examples of different classes from the works of Cruikshank, Delaroche, and Jerome. The fact that historic doubts were sometimes cast on the incidents presented did not invalidate the idea, for it was not the province of art to supply documents. Architecture and music were limited in their power of expression. Painting, in its turn, gave us a situation in history or in life, something beyond a lyric and within a narrative. It was presented to us with a vividness that out-lived all narrative, and might hint the past and foreshadow the future. In France the idealess painter culminated, and had boldly set up his deficiencies as a school and painted *par preference* the most prosaic object in nature—let us say courageously at once, a shiny silk hat. In contrast to these moderns, the art ideas of Giotto, Orcagna, Mantegna, Sandro, Botticelli, Signorelli, Durer, and Holbein were described with great felicity. The idea in art as such belonged more certainly to early Christian or mediæval times than to the renaissance. Yet the three great workers in that change—Leonardo, Michel Angelo, and Raffaele—were as fitted to cope with others in ideas as in other aspects of art, but owing to the times they lived in, to some thing or law not yet appreciated, it was ordained that they concerned themselves, not with ideas, but with a quality new to art—style. Mr. Brown dated the commencement of the art idea in England with Hogarth, but took Blake as the English type of the painter of ideas in art, and devoted the remainder of his lecture to a sketch of that artist's life and work.

CHIPS.

Providence Baptist chapel, in Castle-lane, Bedford, was reopened on Sunday week after renovation, enlargement, and the replacement of the old square pews by light deal benches. Mr. Young was the architect, and Mr. Hull, also of Bedford, the builder.

The following gentlemen are candidates for the office of district surveyor to the Metropolitan Board of Works for the parish for Putney and Hamlet of Roehampton, the election for which takes place to-day (Friday):—Mr. J. B. Badoock, 7, Staple-inn; Mr. C. W. Brooks, 14, Duke-street, Adelphi; Mr. R. H. Burden, 397, Oxford-street; Mr. A. Conder, 11, Queen Victoria-street; Mr. W. A. Large, 23, Queen Anne's Gate, Westminster; Mr. G. McDonnell; Mr. Alex. Payne, 4, Storey's Gate, St. James's Park; Mr. J. S. Quilter, 10, Brunswick-square; Mr. F. Todd, 36, Essex-street, Strand; and Mr. T. W. Willis, 34, Ely-place.

The Mayor of Leicester on Monday turned the first sod of a new public park near the Abbey ruins and the river. The Corporation have bought 40 acres of land for the park, and the cost of laying it out will be £10,000.

The new line from Stratford-on-Avon, in extension of the East and West Junction Railway to the Eversham and Redditch section of the Midland Railway, will be opened for traffic on Whit-Monday.

The Governors of the Scottish Corporation have decided to proceed at once with the restoration of their hall in Crane-court, Fleet-street, destroyed by fire in November, 1877. The plans have been prepared by Professor Donaldson.

ARCHITECTURAL ASSOCIATION.

THE fortnightly meeting of the Association was held on Friday evening, the President, Mr. H. L. Florence, in the chair. Mr. John Cowell was elected as a member. A vote of thanks was passed to Mr. Saxon Snell for permitting a visit to be made last Saturday to the new Holborn Infirmary, on the motion of Mr. Page, who stated that the next visit will take place on Saturday, June 7th (and not on May 31st, as originally announced), and will be an excursion to St. Alban's Abbey. The nominations of officers for next session were read by Mr. Hayes, the name of the proposed president being Mr. S. Flint Clarkson. Mr. Page announced that none of the designs sent in under motto this year for the Association sketch-book had been selected, as they were not considered to be equal to the standard. The envelopes containing the authors' names had, therefore, not been opened.

THE ARCHITECTS' BENEVOLENT SOCIETY.

THE PRESIDENT brought before the members the claims upon them of the Architects' Benevolent Society. The society had not been supported as it should have been, seeing the useful character of the work it carried out, and its committee were now very anxious to raise its fund to £5,000. For this object £1,500 was needed, and Mr. George Godwin had offered to give £100, if 14 others, who need not necessarily be individuals, would do the same. It had seemed to the committee of the Association that this would be a very desirable opportunity to perform a good work by undertaking to provide one of the £100 required. Already every one to whom the subject had been mentioned had put down his name, and between £35 and £40 had been subscribed. The Association was the first body to move in the matter, and he thought they would find not much difficulty in raising the sum required; indeed, he trusted that at the next meeting, a fortnight thence, he should be able to announce that the sum required had been subscribed.

Mr. ASTON WEBB said, all must support this proposition of the President, for Mr. Florence had introduced it to the committee and had backed it by a handsome subscription; he trusted all would make it a point of honour to subscribe to the fund.

THE PRESIDENT announced that the annual excursion of the Architectural Association would have, this year, its headquarters in the city of Wells. Mr. Pink, the excursion secretary, would be glad to receive the names of those who intended to join.

LATE WROUGHT-IRON WORK.

Mr. W. PENSTONE read a paper on this subject. Round the walls of the room were hung numerous drawings illustrative of the subject (a selection from which appears in our photo-lithographic pages), and also several actual specimens of brackets, candelabra, screens, gates, and scrolls, lent by Messrs. Hart, Son, and Peard. Among the manipulative arts connected with architecture, that of the smith appealed, the lecturer thought, as strongly as any to the aesthetic mind. There is a strong sense of individual power and skill impressed on one by the contemplation of works of beauty and ingenuity developed from the rough ore, which awakened to its fullest extent the sympathetic interest forming so important a factor in the constitution of an "artistic" nature. The hand that wrought the interlacing scrolls and flowing foliage centuries ago has left its impression on the work so markedly, that it seems, through them, stretched out to us in the universal brotherhood of Art. Unquestionably there is poetry in the subject; from the days of Homer to Longfellow and Mackay, bards have delighted to sing of the glowing forge and ringing anvil, and their music had furnished the *motif* to the great masters of harmony. Believing the sense of beauty in art to be in a great measure dependent upon extraneous associations and influences rather than of a nature to be analysed and scientifically deduced from inherent qualities contained in the objects contemplated, one is unwilling whilst looking at the productions forming the subject of our consideration, to eliminate entirely the element of sentiment, in order to gain credit for a "highly practical" paper.

The metal work of the Renaissance fully partakes of the incongruities, vagaries, and debasements, common in the contemporaneous

architecture, so irritating to the modern mediavalists and purists, from whose platform it is easy to discover reasons why the greater part of the works of this class should not rank as high productions of art. But speaking generally, as to the art of the period, much interest is awakened and indeed many a lesson may be learned from these very vagaries—the outcome of an age when the increase of populations was leading to a spirit of restlessness, and travel, and the struggles between old formulas and new ideas developed constant incongruities and piquancies in the vigorous life so strongly reflected in the literature and art of those centuries. And in the new motives and fresh impetus given to art-workmanship at this time, may be found ample field and principles for study and judicious imitation, without reproducing extravagancies for the sake of quaintness or making precedent of failures. It is worthy of remark, that whereas in the Earlier Gothic period, the ironwork has a character of its own, consonant with, but not in imitation of, the other architectural details of the time, in its later developments the ornamental forms of wood and stonework, were adopted by the smith, and wrought with wondrous skill and finish, but with a corresponding loss of power. The introduction of sheet-iron into use during the 14th Century, brought into play other tools than hammer and tongs, and although the new form of material was at first used with the simple adaptiveness and propriety so characteristic of the mediæval workmen, the greater ease of manipulation in time led to over elaboration and imitation in lieu of natural treatment of the material. At the end of the 15th Century we find the work of the smith in locks, hinges, railings, &c., with all the detail characterising the contemporaneous stonework. Traceries, crockets, finials, and foliations, are executed by means of overlaying plates in many thicknesses, chiselled, stamped, and chased. But the iron industry was now growing with great rapidity and assuming a more important place than it had hitherto occupied. In the next century the southern forests of Germany and our own timber districts were glowing with furnaces, and with the increased facilities for the production of the metal came increase of power in dealing with it as an ornamental material. In the hands of those artist workmen who, encouraged and protected by the municipal systems, added so much to the power and wealth of the great independent or semi-independent cities of Central Europe, metallic design was developed with a vigour and freedom which left behind the architecture of the age—then in the efflorescent decadence of an exhausted style. And although this branch of work partook of the infusion of Classic detail, with which, as with new blood, it was attempted to reinvigorate constructive design, it did so in a perfectly natural and adaptive manner. For the best examples of the work of the 16th and 17th centuries we must turn to Germany, certainly for the most numerous. The great imperial city of Augsburg and its neighbours seem to have specially fostered the art of the smith. The hinges and other ironwork on doors of the town hall at Augsburg, a building erected at the commencement of the 17th century by Elias Holt, are very good examples of the treatment of flat-iron, cut into scroll interlacing patterns, lined and worked up with the chisel. There is a peculiar character about this class of German work. The curves seem to have been suggested by the tentacles of the starfish. Work of similar character is to be found at the Dom Kirche, which also contains some good railing. This latter, however, whilst showing a close grille of excellent design and a beautiful corona of flowing scroll-work, is spoiled by the extraordinary freak of representing at the bottom a platform surrounded by balusters in perspective on the vertical plane! There are two or three railings of much beauty enclosing the chapels of the great Fugger family in the Cathedral of St. Ulrich, the moulded baluster standards of which deserve attention. The railing enclosing the Augustus Fountain is a very remarkable work, consisting of a much enriched corona of scroll work above moulded uprights. The cloisters of St. Anne's Church also contain some good work. At the Three Moors hostelry in the same city, in the chamber shown as that of Anthony Fugger, is an iron stove, dated 1532, ornamented with scenes from the wars of Maximilian I. Augsburg especially excelled in the use of the cold chisel and in chasing. Besides sword and dagger handles treated in this manner, detached

statuettes were carved out of the hard metal. Considering the much greater adaptability of other and mixed metals for this purpose and the rapid oxidation to which iron is liable, one cannot but consider such labour as in a wrong direction. One of the most elaborate works of this description is now at Longford Castle, near Salisbury. It is a chair presented by the city of Augsburg to the Emperor Rudolph II. It is decorated with small statues and reliefs representing events in the history of Roman emperors, and most highly wrought and chased. It is the work of Thomas Ruker, A.D. 1574. It is of course entirely out of our province to take up the subject of arms and armour, which at this period received the highest decorative skill of the smith, and such works as these may be relegated to the same class. This paper is not a catalogue of the chief works in iron, but is intended merely to point out a few accessible examples which are worthy the attention of the student. At Salzburg, Austria, in the cemetery of St. Peter are several grilles to tomb entrances of the 17th and 18th centuries. The best of these is that of the Zillner family, 1610, a good design with the prevalent round iron scrolls, flat leaves, and repoussée masks. It is this period, that of the 16th and earlier part of the 17th centuries which furnishes the best examples of iron treatment, fully equal to if not surpassing any previous efforts of the smith in Germany, even at the best period of Gothic work. Most of the examples already quoted belong to this era, and much work of the kind may be found scattered over Germany. Nuremberg, as might be expected, contains many specimens. One interesting piece is the railing round the Schoen-brunnen fountain, the work of an Augsburg smith, named Paul Koen. This encloses a fine structure of pointed work, and the feeling in cusplings to cresting and buttressed standards is decidedly that of the Late Gothic, but the character of the foliage and scrolls to standards is of an independent type. The grille itself is of a pattern much used, cross diagonal bars form a diamond pattern, those in one direction being placed square and in the other edgewise, the former passing through the latter. Scattered upon this ground are sprays of foliage and geometrical patterns entwining and interpenetrating the bars. Another example of similar work may be found in Vol. III. of "Architectural Association Sketch-book," in a grille to a house at Frankfort, sketched by Mr. Aldridge, and on the same plate is a drawing of gates to a chapel at Cologne, which is very suggestive in character, the lower part being filled in solid with wood and flat iron. The ancient Nuremberg houses contain many grilles. One very fine one is that to No. 37, Winkler-Strasse. There is a fountain of simpler character than the Schoen-brunnen in the Ebner-Strasse. Riveting in this work is rarely resorted to. In the flat iron, the intersecting bars are halved and welded, and in the prevalent round-bar work they pass through eyes in the opposing stalk. The branches are well welded on, the larger ones often uniting inside a cup terminating the main stem. The lines generally flow easily out of one another, spiral patterns predominating. The round, smaller stalks flatten into sprays of small leaves whilst the larger terminations are cut from the sheet in the form of leaves of foliated masks

These were often painted and gilt or repoussée, and lined with the chisel. Quaint forms recalling,

perhaps representing, the gnomes and dwarfs with which Teutonic imagination peopled the depths of the forest and recesses of the mine, are very generally introduced, being boldly indicated by the chisel in the flattened iron. The work displays a suitable amount of finish, but the marks of the forge are not obliterated by the file. But the most noticeable feature of the Early German Renaissance work is the beautiful flower termination so generally used, and which was a triumph of just conventionalism. The petals, stem, calyx, leafage, and buds are represented in an illustrative and general rather than an imitative manner—a treatment more in accordance with true principles than the closer renderings of specific flowers, beautifully executed as these are found in later work. These terminations severely test the powers of the modern smith in reproduction, being formed by intricate pieces not riveted or soldered, but welded together from the furnace. (Indeed, there are many operations of the old smiths which appear to have been lost, as, for instance, that by which the railings to the tomb of the Emperor Maximilian at Innspruck are formed. Here leafage, undoubtedly of repoussée work has been applied to the baluster-formed uprights in such a manner that it appears as if wrought in one piece.) There is a very careful drawing by Mr. Anderson in the last volume of the A.A. Sketchbook of one of the flowers I have referred to, and I have here (Fig. 5) a specimen of the simplest form.

At Munich some good street work yet remains. The church of Notre Dame formerly contained some very fine enclosures of early 17th century work, but during its restoration in 1860 these were taken out and probably destroyed, a fate that has too often overtaken ecclesiastical work of this description during the earlier stages of the Gothic restoration movement. At Bremm, on the Moselle, there is, I believe, a curious iron pulpit dated 1663, but I have not been able to find any illustrations of it. From the end of the 16th to the middle of the 18th century it was everywhere the custom in Germany to ornament tombs with iron crosses. They have been very generally removed, but in some instances are preserved in the vaults belonging to the burying ground. These were generally painted in oil and part gilt, and have often a small locked box or reliquary at intersection. A good specimen of the general style of these may be seen in the South Kensington collection in the form of a cruciform candelabrum; also some examples of cruciform suspenders used in lighting churches. Cressets or torch-holders and other funeral furniture in wrought iron of the 16th and 17th centuries have been often preserved in churches, and the Cathedral of Cologne possesses some remarkably fine examples of these. There is some good ironwork in the cathedrals of Ulm and Ratisbon. The work of the period which has been dwelt upon is characterised by a boldness and vigour which later became much refined upon. The features and details of Classic art, which in Italy were re-developed with a refinement due to the presence of the ancient models and the character of the people, received at the hands of the northern smith in their earlier introduction a very free translation, in which the element of

what may be termed elegance was often entirely lost, whilst that of power was intensified. (A remarkable exemplification of this spirit in art will be doubtless familiar to students of the great master of the German Renaissance, Albert Durer, whose sketches and adaptations from works of the Italian painters, display a total indifference to their refinements, and exaggerations of their most forcible points.) In truth, until the 17th century the influence of the revival was but little felt in German metal work, the artists in which, taking a departure from the forms of the later Gothic, had formed in the previous century or so a school of their own of great originality. But the Thirty Years' War paralysing the industries of Germany seems to have stopped the full development of this national style, and the country never recovered her pre-eminence in this direction. The work of the latter 17th and 18th centuries succumbed entirely to the classic spirit everywhere triumphant, and except for a somewhat sturdier rendering, there is little to characterise this later work from that of other countries. The execution is always good. We have sketched a small panel and hinge from South Kensington Museum, which shew the usual character in its best forms. Rich work of the heraldic "lambrequin" character was often compiled by various flat pieces, overlaid and welded at the stem, but branched, twisted, and curved in various directions as they develop. In Italy, naturally the return to classical traditions appears at a date anterior to their acceptance in other countries. Thus in the well-known lantern and torch-holder affixed to the Strozzi Palace these forms are adopted at a period when work of the pointed style was being carried on everywhere. They are the work of Niccolo Grasso, about 1480. The warm climate of the South led to the extensive use of balconies and railings and openwork window panels, which may be found in great profusion in most of the Italian cities, especially Venice—mostly of 17th and 18th century date. They are usually of scroll treatment in a combination of flat and round iron with moulded bands, devoid of applied or cut leaf work, but of an infinite variety of pattern, re-entering curves being very generally used. Close diaper grilles with rosettes are, however, frequently met with. In the lighter forms what may be called "riband work" is much employed, the iron used being of the thickness of $\frac{1}{4}$ in., doubling upon itself and confined to the shape required by ties of thin metal. Beautiful chains of this description were used for hanging lamps, and are frequently picked up by the fortunate hunter in brack-a-brack. Stands for majolica bowls are another form in which much fine work was executed by the smith. France possesses some very good forged work, although it is not nearly as plentiful as in Germany. This may be in part owing to the excesses of the Revolutionists, who, however, like our Ironsides, were doubtless credited with more destructiveness than is their actual due. In the wholesale demolition of chateaux and desecration of churches, such easily removable work as iron gates and grilles has doubtless disappeared to a large extent. Paris, however, contains many examples of fanlight open-work, chiefly of late date. Two of these, of the end of the 16th century, are well worthy of remark. One is from a door of the Church of St. Nicolas des Champs, semicircular in form, fixed in two halves in wooden frames; fleur-de-lys ornaments cover the points of contact of the bars and rosette terminations are used, formed by many thicknesses of serrated sheet iron; the initials S. N. and S. J. occur in the centre. A fanlight somewhat similar is to be found in the Rue St. Paul. The Louvre contains a work of the smith which, like our Hampton Court screens, is monumental in character, and affords the best example of this industry in France at its best period—I refer to the two gates in the Apollo Gallery. (Perhaps some of my hearers well acquainted with French architectural literature may be able to refer me to good illustrations of these. I have been only able to discover an engraving of one of them which does not do it justice.) These magnificent specimens were discovered in the reign of Louis Philippe at the Chateau de Maisons, Laflitte, in a sadly neglected state. They are of late 16th-century date, and one is said to be the work of a Frenchman, and the other of a German. They have been very carefully restored, the firm into whose hands they were entrusted having practised their workmen for months on

similar work before taking them in hand—a contrast with the treatment of our Hampton Court screens, which have been very indifferently repaired. The Louvre gates are of a purer Classical type than ours, and the details of construction are better. The structure of the design, however, is too directly imitative of wood paneling, and there is much repetition in the forms. These possess much grace of outline, and the top panel, representing Amorini crowning Time, is a most beautiful composition. At the Lycée Napoléon is a 17th-century grille of good design in five panels—those at bottom being well-filled with a pattern of many parts, the centre ones with open upright bars, and the top large panel occupied by a shield surrounded by flowing scrolls. There are some balconies typical of the 13th-century style at l'Ecole Centrale des Arts, formerly l'Hôtel Salés. In late 17th-century work the lines of the design in iron follow very generally the contortions characterising the school of decoration termed "Rococo," the applied ornament is often of bronze. At Fontainebleau is a wrought-iron railing surrounding the meat of 17th-century workmanship, and similar enclosures may be met with in a few of the chateaux remaining of this period. The Cathedral at Rouen contains a railing of the reign of Louis XIII., enclosing the chapel of St. Eustache. At Naney, in the 18th century, Jean Lamour, smith-in-ordinary to Stanislaus, King of Poland, executed many remarkable works in iron which are amongst the cherished monuments of the ancient capital of Lorraine. They have been illustrated in a special work. At Toulouse, in the Museum Garden, is a well with ironwork of the 17th century of somewhat eccentric design. A similar example of the same period may be found at Mothault in Belgium; and there is one in the Hôtel Cluny, Paris. Window panels of similar character to the Italian ones we have mentioned, and altar rails of like design may be found in provincial towns, more especially in the southern provinces. We have here sketches of some from La Ferté Bernard and Nogent-le-Rotun. The diligent explorer may find some few of the old sign-brackets remaining in Paris and other cities, from which were displayed the trade marks or insignia once in universal use amongst tradesmen, but now used only by publicans and pawnbrokers. These were often of elaborate construction, as the examples now at South Kensington. Also, though now very scarce, there are, I believe, to be found some of the old "Lanternes" of decorative character from which were suspended the oil-lamps used in street lighting, and which acquired so terrible a significance during the First Revolution. A most interesting and quaint work on iron was published in the year 1627 at Laflèche, by one Mathurin Jousse, a provincial working smith, who also issued treatises on perspective and carpentry. It contains a number of designs, chiefly for locks, keys, and similar work, which are marked by great spirit and invention. The original work is very scarce, but it has, I believe, been partially reproduced in facsimile. The elaborate door furniture produced in Italy and France during the 17th and 18th centuries, forms a subject in itself, and has, I believe, been so treated in a volume lately published in Paris. The knockers especially are of great variety and richness, containing often groups of figures executed in the highest style of art, such as the well-known one at the Palace Pisane, Venice, representing Neptune and sea-horses. These, however, belong more properly to the art of the sculptor and founder, rather than to that of the smith. Many examples are produced entirely by chisel and file. But the simpler varieties, such as two I have sketched at Caudebec, will often afford good hints for the treatment of ordinary work. There is a fine knocker brought from Paris, at Barnard's-Inn, Helbern.

In this rapid sketch I can but just allude to the work in other countries. That in the Low Countries assimilates in character to the French, although perhaps heavier in style. At Forêt, near Brussels, in the church of St. Denis, are some good gates, date 1760. At Bruges may be seen some few wrought-iron finials to its many gables; note one in the Rue du Fil, dated 1628. Spain possesses much remarkable work in iron, characterised by the ornateness displayed by its architecture. In Switzerland also some fine work may be found in window grilles. As I have remarked about the German, so in the work of Italy, France, Spain, England, and the Low Countries,

the national distinctions in style are but faintly marked from the 17th century. Scrolls, masks, acanthus, and other leafage, urns, the spear, shield, and sword, and other forms, all modelled on distinctly Classic precedent, are used in a similar manner in all countries to produce works of great richness and beauty, but which often convey a sense of over-elaboration and artificial effects unsuitable to the material. In Germany, as we have noticed, the rendering of this Classic detail is vigorous rather than elegant; in France the facile and versatile spirit of the nation is displayed by graceful combinations of curvature and easy adaptations from antique models; in Holland there is often an affected quaintness; whilst in our own country there is to be discovered a certain sense of fitness—a degree of independence which makes much of our work most valuable and suggestive. But these differences are of so subtle a nature that it would require a much more exhaustive paper than mine to analyse them, and we must remember that the interchange of work and workmen among the different nations tended much to obliterate local characteristics.

I must now proceed to the home view of our subject. The metal work of our Perpendicular Period is of a very high class, though the forms are of marked architectural character. The inclosure to Henry VII.'s tomb at Westminster (in bronze or latten) is perhaps the finest example of such work to be found; and the railings to Edward IV.'s tomb at St. George's, Windsor, is a marvel of elaborate construction. Both of these are probably the work of foreigners, the latter being popularly ascribed to the hand of Quentin Matsys. I have not been able to discover any conspicuous examples of ironwork of the Elizabethan age, though much of the smaller work in lock-plates, hinges, &c., remains. In Exeter Cathedral there is a door-plate in the form of a crown, of 16th century date, and the city itself possesses an interesting relic, probably of early 17th-century workmanship, in some mace-holders of cut and chiselled sheet-iron, coloured red and green, and parcel gilt. The vestry-door to St. Saviour's, Southwark, has a handle in the form of a ring, with lizards on it, of the same date. At Hurst Church, in Berkshire, there is a curious wrought-iron bracket for hourglass, date 1636, painted and gilt. In most of the old Elizabethan mansions much useful work in the form of door furniture, though generally of a plain character, may be found. Eastbury House, near Barking, furnishes some good examples of these. The Ashmolean museum at Oxford has a fine lock plate of a more ornamental description.

I have here some sketches of a work of the Jacobean age which is a very good example of the powers of the English smith. It is a screen formerly separating the pew of the Leversedge family from the Lady Chapel in the Church of St. John, Frome. I consider this specimen singularly happy in design, and delicate in execution. The composition gives due importance to the central feature bearing the armorial shield, while the side panels are agreeably diversified. The general size of main bars is $\frac{1}{2}$ in. by $\frac{1}{2}$ in. or $\frac{3}{4}$ in. The lines of hammered work are not obliterated by sheetwork, although there is quite sufficient of this latter to give a richness to the design. Altogether, there is what may be called a restrained freedom about this piece which is very pleasing. It has recently been added to the valuable collection of ironwork at South Kensington. Later in the 17th Century we come to a series of examples which are probably well-known to all London students, the screens from Hampton Court. They are 12 in number, and were formerly placed at intervals of 50 yards in the fence dividing the palace home park from the garden. They were, however, dropping into decay, and removed to the palace to preserve them. Seven of them have been for some years placed on loan in the Kensington Museum, and some of these have recently been placed in the building at Bethnal-green. Huntingdon Shaw, blacksmith, of Nottingham, is recorded as the artificer who constructed them about 1695; his monument may be seen in Hampton churchyard. The screens are of large dimensions, about 13ft. wide by 11ft. high, and altogether exhibit a surprising amount of labour and ingenuity. The general construction of the whole series is on one pattern, but four of them are of richer detail than the others. Panels 2ft. 4in. wide, formed of uprights 2in. square, filled in with a pattern of 1in. bars, and sup-

ported by stays, form the supporting standards on either side. Between these is a flowing composition of elliptic scroll work, with bold appliqué foliage and flowers, surrounding a panel about 3ft. square, which in the four principal screens enclose representations of the national emblems, the rose, thistle, and harp, the remainder being filled in with a diaper pattern. Above this is a heavy swag or chain of flowers, pendant from the beaks of eagle-headed scroll terminations, and crowning the whole is a foliated mask with a figured and tasselled apron. The BUILDING NEWS of 1877* contains a good illustration of one of these screens. All the detail is most wonderfully wrought out, the small rose buds and sprays being represented with great fidelity to nature, as if in imitation of the work of Grinling Gibbons in wood. But a naturalistic treatment, however suitable for the material in which the latter artist worked, is not at all so for iron. The ornament is almost entirely of an appliqué character, the larger scroll ends are even cased with sheet-work. It is very surprising that, notwithstanding the care displayed in the formation of these details, the whole is very badly put together, and it is no wonder that the influences of time and weather were speedily bringing these fine works of art to ruin. Very few of the scrolls or stems are welded at their junctions, but are simply united by iron tongues and pins, the heavy strains on which have in some instances caused them to give way. The leafage too, which in the most ordinary gate-work of this period was always welded to the stems from which it springs, is here merely riveted or screwed, the larger branches in several pieces. Notwithstanding such defects, however, these works must always be objects of admiration from the boldness and originality of their design, and the evidence of patient skill in their production. There are other productions of the smith at Hampton Court Palace well worthy of attention, such as the balustrading to the King's and Queen's staircases, the work of a Frenchman, though doubtless from designs by Wren. Of great importance, and doubtless familiar to most of you is the ironwork of St. Paul's Cathedral, by the same artificer as that last-mentioned one, Tison, a Protestant refugee. These have also been illustrated in the BUILDING NEWS.† The hand of the master designer is here very apparent, although probably very much more was left to the workman than would be the case under our present system. The gates to the choir are noble in design and proportion, and exhibit a refinement, compared to the Hampton screens, which may be partially due to the nationality of the producer. In those facing the nave, exception may be taken to the imitation of fluted pilasters in open work, and to the flattened flaming urns at the top. I do not think the urn-shaped standard terminations at all an inappropriate form, but I do consider them unpleasant if in the flat, especially if the smith attempts to put them in perspective, and more especially when he represents them as if seen from the clouds, as in the Leversedge screen.

The side gates display neither of these defects, the panelling being filled with close scroll work, and the corona containing scenes for large candles, 23 to each screen. Nevertheless, we lose the vertical treatment in the gates, which gives so much more value to the flowing work above in the others. The grilles at back of stalls, the balustrade to gallery round dome, and the work to geometrical staircase are, especially the latter, worthy of study. In some of the City churches yet remaining may be found interesting pieces of ironwork. The church of St. Paul, Covent Garden, contains some good work of a subdued design, harmonizing well with the remarkable structure. Many of the entrances to parks, public buildings, and mansions of the reigns of Queen Anne and the early Georges display noticeable gate work on a large scale. A list of these, if made, would be of some length, but useful to the student. Amongst the more remarkable, we may mention the gates to Clarendon Press at Oxford, 1712, these at Trinity and New Colleges in the same city, the gates to Temple Gardens, 1730, and to Gray's-inn, 1723. In the older suburbs of London, and in many provincial towns, one's attention is often drawn to the home-like dwellings of the last century, with fore-courts

enclosed by wrought-iron railings and gates. Chelsea, Hampstead, and Clapham, contain many examples, and through the medium of the Association sketch-books I have been able to place many illustrations upon these walls. (See lithographic illustration.) It is amongst this domestic work rather than the more ambitious efforts of the smith, that the student of design will find most valuable motives and ideas. There is always a sense of fitness for the purpose designed, and generally a temperate use of ornament other than constructional; that is, the hammered bars and scrolls are not overlaid with sheet work, but depend upon the variety of curve and pattern into which they are wrought for richness. The natural structural composition of an open enclosure, that of upright bars, is seldom lost sight of, the leading lines being vertical and the scroll work being kept in subsidiary panels, or confined to the heads and principal standards. The gates themselves are often quite plain, the ornament being confined to the frame surrounding them. The flowing work, of beautiful design, gains much in value by being thus temperately employed, and the whole composition embellishes the building of which it forms a feature without disturbing its repose. Often unpretending enough, such work impresses one as that of men who gave their hearts to it, though it was usually produced in humble smithies. The careful and often excellent work turned out from our modern art factories somehow seems to lack the power of interesting you in its producer as this old work does. Doubtless one reason is that it is too perfect. You never see a curve gone slightly wrong, and the leaves are cut too closely to pattern and too well balanced. You can picture the old smith pausing to consider which way the curve should now be turned or what twist to give the spray of leaf; possibly arguing a point of broken flexure with the idling critic, or interrupting his work to shoe a passing traveller's horse, and hear the latest news of Marlborough's wars the while. One's mind would scarcely dwell upon the art-metal workman of the present day tracing down on the sheet careful details of elaborate foliations.

Before the opening up of the northern and midland coalfields, smelting operations were carried on in such forest districts as still afforded abundance of timber. In the reign of Elizabeth it was foreseen that the great demand for fuel to feed the increasing number of furnaces would tend to the rapid exhaustion of growing wood. Various repressive statutes were enacted prohibiting the establishment of works altogether in some districts, and limiting them in others. The Weald of Sussex and portions of the neighbouring counties, were the nearest source of supply to the metropolis. The earliest specimens of castings came from this district, and the "Sussex iron," in the form of andirons, or fire-dogs and fire-backs, is well known to the collector and dealer in "antiques." The decorative work in the fire-backs is especially noticeable in the 17th and 18th centuries, some very elaborate compositions being produced, but always marked by a suitable or plastic treatment. The fine railings around St. Paul's, now being refixed, were the produce of a foundry at Lamberhurst, in Kent, and are good specimens of the right treatment of cast-iron railings. The Sussex furnaces were finally extinguished in the middle of last century. Their history is an interesting one, and may be found in the volumes of the "Sussex Archaeological Journal." I have not the space to go into the question of cast-work, to the abuse of which useful manufacture we owe the pretensions, vulgar, and uncomfortable accessories which have disfigured our architecture to so great an extent. The subject of iron design in the present day has been taken up by abler hands than mine. I only feel it incumbent on me to urge the necessity of making oneself thoroughly acquainted with the different phases it has gone through in the periods I have been dwelling upon. In the earlier German, and the simpler forms of our own 18th century work, we have models of a natural and, therefore, artistic treatment of material which will repay close study; and I am sure each of these periods might be advantageously treated of in a more detailed and technical paper than I have been able to put before you. I have now only time to indicate one or two points wherein I think such work offers useful guidance to the designer. The most natural way of employing iron in an

* May 11th, p. 464, Vol. XXXII.

† Published May 18th, 1877, p. 488, Vol. XXXII.

independent manner is surely that of an arrangement of bars or lines, connected together in a constructive manner to combine lightness and strength. These bars may be manipulated in various ways: of sections round or square, or moulded; and the combinations of curved and straight lines offer an endless variety of patterns. Decorative work of lighter form, in which the sheet-iron is brought into play, may be applied, to a certain extent only, without interfering with the sense of stability given by the preponderating forged work; and this is always the principle of the earlier smiths, though generally lost sight of in the more important works of the later centuries, when the forged work was often but a constructive frame concealed by the application of decorative forms. Large mouldings imitative of those in stone and wood were formed out of sheet-iron, inclosing the bars supporting the structure, whilst cut and beaten work, highly wrought and made up into imitations of natural foliage, human forms, draperies, and other objects, frequently attached by rivets only, crowded the whole composition. Now in the German work the figures which were often introduced were usually continuations of the scroll bar, out of which they were worked in the solid forming part of the structural composition, though often with wings and foliations of sheet work attached. (See Fig. 6 and lithographic illustration). The

FIG. 6

leafage grows naturally out of the main lines, to which it is kept in subordination. The terminations of the voluted scrolls, are points of the design which fitly receive ornamentation, and this detail alone is deserving of attentive study. Although the use of applied sheet work in the form of flower or geometrical rosettes—is here quite a legitimate form of enrichment—we find that, very generally, sufficient effect is produced by simple treatments of the hammered bar. A great variety of these may be evolved out of the two principles of spreading the end—in one case in the depth of the bar, in the other in its width (see diagrams Figs. 1 and 2).

FIG. 1

and flat iron are generally found used together in our English gate work, giving a diversity

to otherwise similar forms. By welding an additional metal (Fig. 3), and by a combi-

FIG. 3

nation of the two principles—with alterations to the sectional form of bar, many other developments may be obtained, of which we have here one or two examples, chiefly German. Or the termination may be hammered and chiselled, or stamped (as usual in modern work) into dog-heads or geometrical patterns. In all cases where exposed to probable rough treatment, these methods are preferable to the use of cut and beaten ornament. As an example of consideration of fitness for purpose, I should point to a gate of German work now at South Kensington. It is of a close diaper pattern, a fleur-de-lis ornament being formed on the upright bar, by stout hammered foliations welded on. The points, of which there are many, are all carefully turned well inwards, and protected by the enclosing bar work. Rounded clips are used, and it is quite possible to lean or be pushed against the gate without risking tatters—a desideratum which is too frequently lost sight of by the modern designer. As a general rule, I do not think ordinary protective enclosures require highly ornamental display. The area railings of last century, which are familiar to us all, with their standard panels at intervals in the assemblage of square bars, are to my mind much more satisfactory in a long frontage than elaborate patterns. The bold forms of the spear-heads and occasional scroll ramps, with the now obsolete lamp-brackets and torch-extinguishers, quite sufficiently relieve the designs from tameness—a failing which this material suffers less than any other, and which is often most conspicuous in the most ornate work. There is often more character in a simple forging than in many pretentious patterns drawn from the sand mould, as a comparison between the spear-heads I have mentioned and the usual run of cast railing will testify. And I would repeat again that the great lesson which all old work impresses upon one is that the refinements of the file, scissors, and pliers, should not be allowed to emasculate the vigour produced by hammer, tong, and chisel. In what I feel to be rather too sketchy a paper, my endeavour has been to interest the architectural

student in a subject worthy of careful attention. The present phase of the somewhat erratic course by which modern art progresses has brought the periods I have been referring to to the front. Whether it is a mere passing craze—as some would have—and we are to return to the earlier work; or whether, having run through the styles of all centuries, from the 12th to the 18th, to get our hands in, we shall now satisfactorily develop a 19th century school of distinct character, is a question I should not care to discuss. But of this I am sure—that all earnest, laborious work, of whatever age or style, is worthy of study, and the lesson of thoroughness may well be learned in these productions of the forge. “The smith also sitting by the anvil and considering the ironwork; the vapour of the fire wasteth his flesh, and he fighteth with the heat of the furnace. The noise of the hammer and the anvil is ever in his ears, and his eyes look still upon the pattern of the thing that he maketh. He setteth his mind to finish his work and watcheth to complete it perfectly.”

BILLS OF QUANTITIES: THEIR PROPER RELATION TO CONTRACTS.*

(Continued from p. 567.)

I SHALL now take up the second part of my subject, and

II.—Examine critically the distinctive characteristics of the three systems just described. First, then, let us criticise the London system with its modifications as practised generally throughout England and Ireland. Not many years ago, before it was customary to supply quantities, the London mode of procedure was theoretically right, though somewhat inconvenient for contractors—the architect showed and described exactly what was wanted and left the contractor to find out by any means he thought proper what the work would cost. The issuing of the quantities by the proprietor or his agents, however, makes a fundamental difference. One good feature remains, namely this, that if no changes are made after the contract is entered into the proprietor knows exactly, before the work is commenced, what he will have to pay for it. This feature, however, is not peculiar to the system. Before it became customary to supply quantities, contracts were equally definite, and it would be rash to conclude that they were less favourable for the proprietor; on the contrary, the customary allowance for contingencies has now probably been increased, and in most cases the definiteness is only obtained at an extravagant cost; and I say so although I by no means regard it as a thing of little consequence. Now I fear you will consider me to be extravagant when I declare—as I am constrained to do—that I have failed to discover anything else about the London system and peculiar to it which merits commendation. Nor is this unsatisfactory state of matters to be wondered at, because you have made the radical mistake of adhering nominally to a principle which practically you ignore, while you have gradually introduced a practice which, if followed to its legitimate issues, is antagonistic to it; and you have thus insensibly drifted into a false position. Hence naturally the confusion as to the relative responsibilities of parties and the inconsistencies and contradictions of legal opinion on the subject. The root of the evil—and it has many branches—seems to be the illogical, and I think, illegal, repudiation of the responsibilities necessarily associated with the act of supplying quantities. It is clear that logically and in equity the party estimating, not having any voice in the selection of a surveyor, and having no means of testing the accuracy of the documents given him for his guidance by the proprietor through his agent the architect, ought to have recourse against the proprietor if he can prove that he has been either unintentionally or deliberately misled. This you deny, and this denial leads to many objectionable consequences. Traditional usages and prejudices bind you to the old theory that it is the contractor's look-out to see that the quantities are accurate,—although you know perfectly well that in ordinary circumstances it would be absurd to expect him to do anything of the kind, and that in point of fact he takes the accuracy of the quantities for granted either because he has faith in you, or faith in the

* A paper read by JOHN HONEYMAN, F.R.I.B.A., Glasgow, before the Royal Institute of British Architects, May 19th, 1879. (See pp. 565-6.)

These methods, in their simplest form with a parallel treatment, and a variation of round

surveyor, or perhaps because he has faith in the chapter of accidents and cannot have a chance of contracting unless he accepts what you give him for his guidance. As a last resort, you take refuge in this expedient—you declare that you are not, or, that you are not to be held to be, responsible, and you roll the responsibility over upon the surveyor, and tell the contractor to pursue him if he has any cause. Now it is quite right that the surveyor should be responsible for the accuracy of his work, but not to the contractor; for observe the natural result of such an arrangement, the preparation of the bills of quantities and all responsibility connected therewith is virtually handed over to men whose direct interest it is to victimise your client to the greatest possible extent. This is putting it broadly, but that is necessary for illustration; it is still literally true. You will not understand me to impugn the honesty of quantity surveyors as a profession, far from it—indeed my own experience has led me to form the very highest opinion of their probity; but I wish here to bring out clearly the actual relation of the parties and the consequent results. The surveyor and the contractor alone are benefitted by the quantities being excessive; every penny unnecessarily added to the contract price by full measurements is a direct gain to both. The contractor is not even deterred from taking full advantage of such errors by the fear of losing the contract, because he knows that his fellow-offers have all been supplied with the same quantities, while the surveyor being held to be the servant of the contractor, paid by and responsible to him, has obviously most powerful inducements to keep on the safe side with the measurements, to the direct prejudice of the proprietor, who has absolutely no check upon him. This, gentlemen, is the position in which apparently you are quite content to leave your clients. It appears to me that your interference with the contractor has either gone too far or not far enough. In the old-fashioned system of estimating the experience of offerers came into play as a safeguard against excessive cost, but having departed from this, abolished competition as a check on the accuracy of quantities and made the amount of the offer to turn on the mere variety of rates, you take totally different ground, and ought to be prepared for a change of aspect. In the altered circumstances one or other of two things seems to be indispensable—either the absolute accuracy of the bills of quantities must be guaranteed, or some new arrangement must be adopted by which the interests of the proprietor, as well as those of the contractor, shall be secured in spite of inaccuracy in the bills of quantities. Now, the first of these alternatives is hardly practicable, and, as far as I am aware, you have made no attempt to face the second.

It is probable, indeed natural, that the London system and the Edinburgh system, which is not essentially different, should upon the whole work smoothly and satisfactorily. It throws no undue burden upon the architect, the contractor and surveyor have, as we have just seen, good reason to be satisfied with it, while the proprietor, however adversely affected, knows nothing whatever about it, and is content to pay what his architect certifies to be justly due. The absence of friction in the working of such a system is obviously no indication of its harmonious adjustment; and the helplessness of proprietors and their complete dependence upon us for protection ought to appeal very strongly to our sense of duty and encourage us to grapple with the difficulties of the situation.

I must not pursue the subject further under this head, but this is of the less consequence, as I shall have occasion to refer to some other defects and anomalies when treating of the Edinburgh system which is affected by the same vicious principle of undefined or empirical responsibility.

Second.—The Edinburgh system, in so far as it provides for the modification of the contract in accordance with the rates in the schedule, differs from the English system as generally practised, but it affords little (if any) further protection to the proprietor. The question of responsibility is more boldly dealt with, but not more successfully. The measurer expressly states in the schedule that its accuracy is not guaranteed—that is, of course, either by the measurer or the proprietor—and contractors are therefore requested to satisfy themselves on that point, which is simply absurd. Practically the measurers take care to measure the work fully, and the contractor adds a percentage for contingencies and takes his chance of being rightly guided to the cost. Now you will observe that to the extent of this fulness and this

contingency percentage, the proprietor is a loser, he gets no value for either. But these are small matters; there is no effective check on the omission of portions of work which although embraced in the schedule may have been inadvertently left out of the specification, or of works put into the schedule by mistake. Suppose, for example, the measurer inadvertently doubles the number of cubic feet in the stone foundations, the contractor—executing the work to the full intent and meaning of the drawings—would pocket the value of the double quantity of foundations without anybody but himself being a bit the wiser. Here, again, the unfortunate proprietor alone would be the loser, and his case is indeed a hard one; first he pays the measurer, then he pays for everything that is done, and he also pays for everything mentioned in the schedule, even if it has not been done, that is of course assuming that no alteration has been made on the plans and specifications by order of the architect.

It may be said, indeed, that there is every likelihood that errors to the prejudice of the proprietor may be balanced by others in his favour, but granting this—granting that the surveyor is as likely to make a mistake the one way as the other—observe where this doctrine of compensatory errors must lead you. There is a chance of errors being made which shall balance each other, but on the other hand there is hardly any chance that two such errors as I have noted (and it is not an imaginary illustration) shall be made in one bill of quantities, it would say very little for the surveyor if they did, but even the assumption that they may does not relieve you from the difficulty, because while it is quite true that they may balance each other there is at least an equal chance that they are both in favour of the contractor or both in favour of the proprietor. If however you admit, as doubtless you will, that a surveyor only makes such serious mistakes as this occasionally, then it necessarily follows that while his first mistake seriously injures one contractor, his second may as materially benefit another, but the thought that this is likely to be the case can hardly be expected to afford either compensation or comfort to the man who has suffered. A different system is required to protect the contractor in one case and the proprietor in the other from serious wrong; it is a most unscientific procedure to relegate such a function to chance.

But let me illustrate another set of difficulties which the system cannot satisfactorily deal with by an actual case. In a town, which I need not name, two banking companies resolved to erect new offices. They employed the same architect and the sites were contiguous, but in everything connected with the planning and contracting for the buildings they acted independently, so much so indeed that they employed different measurers. It was arranged that the wall separating the two offices should be a mutual or party-wall, but inasmuch as complete plans had to be made for each bank, the party-wall of course had to be shown on each set, and being so shown it was in due course measured by both measurers. Now it so happened that the same contractor got the contracts for both buildings, and it never seems to have occurred to anyone till the work was done, that by his contracts he had exactly twice as much for the party wall as he ought to have had—he had erected both buildings according to the plans and specifications, but he had erected only one party-wall, and was entitled to payment for two. The contractor refused to submit to a reduction on the ground that he had offered to do the work for a lump sum. He also pleaded that for some other portions of the work the quantities stated in the schedule were insufficient. Finally it was agreed that the whole work should be re-measured in accordance with the Glasgow system, under which no such difficulty could have arisen. In this case it will be observed that the final arrangement was facilitated by the architect having in his hands the priced schedules according to the Edinburgh custom.

The remarks I have made on the English and Edinburgh systems evidently point to this conclusion, that both are generally advantageous to contractors at the expense of proprietors, and that this state of matters is tolerated simply because proprietors do not understand the subject, and architects, on whom they rely for protection, have not decided—many have not considered—what measures of reform are desirable, or practicable. Cases in which contractors are the victims do sometimes occur, but they are comparatively rare; because, as a rule, con-

tractors look after their own interests in time; and it may be, as in the case of the Worcester Guildhall (to which I shall further refer), succeed in getting an arrangement made which relieves them but subverts the system. There is no hope for them except by such subversion; and where the systems under review are strictly enforced, most of us have known cases of extreme hardship—as they are called—but which would be more accurately described as cases of gross injustice, in which contractors have been refused payment for work which to the certain knowledge of both the proprietor and architect was not provided for in the estimate, and the value of which was deliberately withheld from the contractor on the plea that he was bound to do the work according to the plans and specifications, without reference to the quantities. In such circumstances the case of the contractor is rendered still more hopeless and helpless if the architect is also the measurer and the sole arbitrator. Such a combination of functions is generally to be deprecated, but it is utterly unjustifiable when there is no remeasurement of the work, and its legality would seem as questionable as its expediency. It seems to me an extraordinary thing that any law court should recognise or respect the pretensions of an individual who claims to be at once the accused and the judge, a party in the arbitration and the sole arbitrator. By a recent decision, however, in the case of *Stevenson versus Watson*, in the Court of Common Pleas, it appears to be ruled that an architect may so act; and that because he must exercise “judgment or opinion” in two of these capacities, he shall be utterly irresponsible for his conduct in the third. That at least is how I understand Lord Coleridge’s judgment in this case: the quantities taken out by the architect and the additions and omissions measured by him may be grossly inaccurate, but because he has to exercise “judgment or opinion” as judge and sole arbitrator in his own cause, the contractor must be debarred from challenging his accuracy, and must be left helplessly at his mercy. Of course in the case in point there may actually be no inaccuracy. I express no opinion on that subject, not having seen the arguments; but the above inference seems to be warranted by the judge’s opinions. I am tempted here to refer to a remark which fell from Mr. Justice Denman. He said: “Ordinary acquaintance with building contracts showed that an architect could not be regarded as a mere easter-up of figures, and ought not, therefore, to be held liable for negligence where a mistake in figures or measurements occurred.” That is a strictly fair and accurate statement of an architect’s position; but it is not a strictly accurate statement of a measurer’s position. The latter is clearly responsible for the accuracy of figures and measurements, and the architect-surveyor cannot escape from this responsibility by the mere assumption of the two-fold duty without great injustice to contractors. In such a case as this of *Stevenson versus Watson*, it may for ever remain doubtful whether the contractor is justly treated or not; but here again, as in my previous illustration, the remeasurement system would clear away all dubiety, and prevent all chance of complications and lawsuits, thus standing out in marked and favourable contrast with the prevailing systems in England and Edinburgh.

The grand obstacle to the satisfactory working of these systems as at present practised seems to be the impossibility of securing either an effective attachment of responsibility or the substantial results of its due recognition. While some legal authorities maintain that the measurer is responsible both to the proprietor and the contractor, others hold that he is responsible to the proprietor only, who is responsible to the contractor. This latter view seems most consistent with the well-known legal principle that one cannot at once “approve and reprobate.” If a proprietor issues a schedule of quantities as a safe guide for a tradesman, from whom he wishes a tender, it seems most consistent both with sound law and sound common sense, that he should bear the consequences of inaccuracies which might prejudice such offerer; otherwise contractors might be systematically swindled with impunity. But at present special agreements in violation both of common sense and law come in to cause confusion and seeming contradiction in legal decisions. Such *ex parte* contentions however can hardly be justified, and at all events it will generally be found in practice that while proprietors are not likely to hear much about

quantities which err by excess, they are sure to find the burden of responsibility for any serious deficiencies by some means or other rolled over upon them. In this connection such a dispute as that which recently arose regarding the contract for the Worcester Guildhall is instructive. In this case, which was reported in the professional journals about six months ago, it is the contractor as usual who discovers that he is aggrieved. He demands a readjustment of the contract on the ground that the quantities supplied to him for his guidance in making a tender were inaccurate, which he is prepared to prove. This seems a most reasonable demand, but he is met with the plea that the bills of quantities were not referred to in the contract. This plea, however, was not maintained and ultimately a new arrangement was made with the contractor; the proprietors no doubt in this case recognising the manifest absurdity of expecting the tradesmen before offering to satisfy themselves as to the accuracy of the quantities. It will always be extremely difficult for proprietors to get rid of the responsibility of their own act in issuing quantities, it ought to be impossible for them to do so; and many cases such as the above prove that in addition to other burdens which the present system lays upon them they may at any time be called upon to submit to a "scientific rectification" of the contract at the instance of the contractor; and this notwithstanding that theoretically they are not responsible. As we have seen, the payment of the surveyor by—although it is really only through—the contractor is held to make him the contractor's servant and so responsible to him. I have already shown how prejudicial this is to the proprietor's interest, but besides that it is not a straightforward arrangement, and, as we should expect, misses its object. The truth is that the full acceptance of this responsibility by surveyors would in most cases be of not the slightest avail either to the proprietor or the contractor, because obviously a guarantee of accuracy is valueless unless the guarantor has adequate means to meet claims which those to whom he is responsible may legally prefer, or rather substantiate. Now I fear both proprietors and contractors would stand a very poor chance of getting two or three thousand pounds—or even two or three hundred pounds—from the average quantity surveyor, however valid their claim; and if so it is clear that this attachment of responsibility is merely fictitious. Some have proposed that architects should be responsible, but under the present system, with which we are at present dealing, architects are not involved unless they think proper to involve themselves by acting as surveyors—a practice which, under present circumstances, is probably as objectionable as if they also acted as masons or joiners, as some "architects and builders" do. Because they necessarily put themselves into this equivocal position: they are liable as any time to be pursued by the contractor, who, theoretically, is their master; and surely a contractor can make an action-at-law a more powerful lever for moving the architect as he pleases than a direct bribe. On the other hand the architect-surveyor alone can discover and expose blunders of his own which prejudice the proprietor who is also his client, and if the exposure of such blunders would involve him in a loss of several hundred pounds I leave you to estimate the chances of such an exposure being made. The position of the architect as the impartial arbiter between the contractor and proprietor is one of sufficient difficulty and delicacy without the interference of such complicated responsibilities, the effects of which, on average human nature at least, must be vicious and demoralising.

Upon the whole, I think it must be conceded that the English and Edinburgh systems are inconsistent with any intelligible theory of the proper relation of parties, and that the practical outcome of both is this:—To the proprietor, unproductive expense, indefinite responsibility, and liability for payment of work which he does not get, but which has been either inadvertently or purposely measured in excess of what the plans and specifications require; to the contractor, great facilities for estimating, for obtaining payment for everything which he does, and for obtaining payment for much which he leaves undone.

(To be concluded.)

The International Telegraphic Congress will open in London on June 10th.

Building Intelligence.

BEARPARK.—On Tuesday the new Bishop of Durham consecrated the Church of St. Edmund, King and Martyr, at Bearpark, near the city of Durham. The style adopted is Early English. The materials used in the construction of the walls are specially made red fire-brick, with white freestone dressings. The accommodation is for 270, and the cost of the structure, independently of the churchyard wall and gates, &c., has amounted to about £2,300. Mr. George Gradon was the contractor for the whole of the works, which have been carried out from the designs and under the superintendence of Mr. C. Hodgson Fowler, F.S.A., Durham.

BRADFORD.—The new chapels erected by the directors of the Undercliffe Cemetery are now completed. The new buildings are erected in the Early English style, the two chapels being similar in design. A handsome *fiche* or turret, rising to the height of 77ft., surmounts the roof, being situate at the intersection of the nave and transepts. Externally and internally the walls are composed throughout of sandstone ashlar from the celebrated Calverley quarries, and each pile is roofed in with the best green slate. Internally the chapels are 46ft. long by 25ft. wide, the mortuary chapels being 26ft. 6in. long by 10ft. wide; and the vestries 10ft. long by 9ft. in width. The height to the ridge of the roof is about 37ft. The windows and glazed work generally have been supplied by Messrs. Camm Bros., of Smethwick, near Birmingham. The aisles of the chapels, also the floors and walls of the mortuary chapels, are laid with coloured tiles of appropriate design, supplied by Messrs. Maw and Co., of Broseley. The contract for the whole has been carried out by Mr. Coates Murgatroyd, of Idle. The designs were furnished by Messrs. W. and R. Mawson, of Bradford; the carrying out of the works having been intrusted to Mr. J. S. Wilson. The cost of the whole will be nearly £8,000.

EDINGTON.—The parish church of St. George, Edington, was reopened by the Bishop of Bath and Wells on Tuesday week, after having been entirely rebuilt. The plans and specifications were prepared by Messrs. Down and Son, of Bridgwater; and the nave has been built by subscriptions at a cost of £1,200, the expense of the chancel being entirely met by Miss Westmacott. The new building is in the Perpendicular style, and comprises a chancel, organ-chamber and vestry combined, nave with bell turret, and transept. The walling is of lias stone, and the copings, arches, and other dressings of Ham-hill stone. The flooring throughout is of encaustic tiling, supplied by Messrs. Maw and Co.; and a new bell has been furnished by Messrs. Warner of Co., of London. The seats are of pitch-pine, and accommodate 250 people. The work has been carried out by Messrs. Merrick and Son, of Glastonbury.

GLASGOW.—Mr. Frank Matcham, Rugby-chambers, Bedford-row, W.C., having been commissioned by the Central Halls Company (Limited) to submit designs for the erection of a new theatre in Sauchiehall-street, has been appointed architect, and the building is now in course of construction. The principal entrance (through the grand hall and staircase) is in Sauchiehall-street, with minor approaches and exits in Renfield and Renfrew-streets. The auditorium consists of orchestra-stalls, pit-stalls, and pit on the ground-floor, with dress-circle and boxes above, and balcony and gallery over all. In addition to these the architect provides spacious crush-rooms, ladies' and gentlemen's retiring rooms, arranged in a most convenient manner, together with smoking-saloon and refreshment buffets in direct communication with all parts of the house, and at the same time kept strictly private. The theatre will be fitted up with all the most modern improvements and comforts (special attention having been paid to insure ventilation), and the whole design has been most carefully considered with respect to providing ample exits for any emergency by a sudden panic.

HALWILL.—The parish church of Halwill, Devon, was reopened on Holy Thursday, after being rebuilt. Formerly the church consisted of simply a nave and chancel, with a tower and porch. This building was raised to the ground,

with the exception of the tower and porch, and the additions comprise a chancel, transepts, and vestry. The church has been rebuilt in the Early English style. The new chancel is built beyond the limits of the old chancel, while the walls of the nave have been rebuilt on the former foundations, and the old windows have been preserved. The dimensions of the edifice in its restored condition are—nave, 38ft. by 16ft.; transepts, 36ft. by 13½ft.; chancel, 19ft. by 14ft.; and vestry, 8ft. by 14ft. The walls are about 14ft. high, and the roof has a 12ft. rise. Local stone has been entirely used for the walls, which are covered on the inside with parian stucco, tinted red. Minton's encaustic and glazed tiles have been used for the floor. The roof is of red deal, oak stained. The seats are of pitch-pine, with oak bench ends. The same pulpit remains, the panels having been restored and new oak piers supplied. The old church accommodated 100 persons, whilst the new building is designed to accommodate 160 people. Mr. Hooper was the architect, and Mr. White the builder.

LEEDS.—A new chapel at Roundhay-road, Leeds, in connection with the United Methodist Free Church, was opened last week. The new church is designed in the Romanesque style. The whole of the outside ashlar work is of Meanwood stone, with Meanwood and Potternstone wallstones. The inside woodwork is of pitch-pine, varnished. The heating is by hot water. The works have been executed by Messrs. Craven and Umpleby, of Leeds, from the designs and under the personal superintendence of the architect, Mr. D. Dodgson, Park-row, Leeds. The church will accommodate 600 persons. In the schoolroom, underneath the chapel, will be accommodation for 250 scholars.

CHIPS.

The parish church of Brailles, which has been under restoration since 1873, will be reopened by the Bishop of Worcester on Friday, the 20th June. On the previous day, June 19th, the new church of SS. Peter and Paul, in the hamlet of Winderton, will be consecrated.

The restoration of Wakefield parish church is steadily progressing. At the present time the south-east window has just been taken in hand by Mr. George Fawcett, the contractor; and the organ is being reconstructed and enlarged by Mr. Arthur Kirkland, of Wakefield.

The members of the West Riding of Yorkshire Finance Committee of Magistrates met on Saturday at Wakefield for the purpose of appointing a deputy-surveyor for the West Riding. The salary is £400 a year, and 143 candidates offered themselves. It was resolved to recommend to the county magistrates at the next quarter sessions to appoint Mr. Joseph Vickers Edwards, aged thirty-one, at present borough surveyor of Burnley. Mr. R. S. Dugdale, deputy borough engineer, of Salford, was second on the selected list.

The parish church of Frampton, Dorset, is being further restored at the expense of Mr. R. B. Sheridan, of Frampton House, by the alteration of the north aisle so as to correspond with the south aisle added seven years since. The work is being done by men on the estate, the carving being done by Mr. Benjamin Grassley, ecclesiastical sculptor, of Dorchester.

The Roman Catholic chapel of SS. Peter and Paul, Mawdesley, near Preston, was reopened on Sunday week, after having been decorated by Mr. R. Park, of Preston. On the high altar has been placed a picture representing the Adoration of the Magi, painted by Mr. Rossi, of London.

Memorial-stones of a new Wesleyan chapel have been laid at the Broadway, Roath, near Cardiff. The chapel will seat 920 persons, and is Gothic in style; it is being constructed of Newbridge stone, with Bath dressings, and the chief façade will be flanked by turrets. A deep gallery will surround three sides of the chapel. The total cost will be £5,500. Mr. Faulkner is the architect.

At last Friday's meeting of the Metropolitan Board of Works drawings submitted by their architect (Mr. Vulliamy) for a new fire-brigade station to be erected in Tooley-street, was approved. The death of Mr. Horace Field, the district surveyor of Putney and Roehampton, having been announced, it was decided to advertise in the usual way inviting candidates for the appointment; the election will take place to-day (Friday) at noon. A formal representation under the Artisans' Dwellings Act, 1875, as to the unhealthy condition of a certain area in Limehouse, was received from Dr. G. A. Rogers, medical officer of health for that parish.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation render it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Two-pence, of all booksellers and news-vendors. Post free 2½d. Office: 31, Tavistock street, Covent-garden W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements is, per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) for any part of the United Kingdom for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33s. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—M. E. and Co.—S. G. Co.—G. N.—P. O.—B. H. and Co.—R. W.—S. F.—V. of S. M. I.—T. R. and Son.—W. H. S. and S. D.

STONE AND MARBLE. ("E. F." wants to know the addresses of quarryowners from whom he can obtain Hop-ton Wood stone and Derbyshire marble. Any such would do well to make their existence known in the usual manner in these pages.)—ASTI-HUMBURG AND J. ELLIS. (It is, of course, abominable that such people should be allowed to practise a profession of which they have no knowledge; but what is to be done or said while people are so foolish as to employ them?)

Correspondence.

MR. OLIVER AND THE NEWCASTLE FREE LIBRARY.

To the Editor of the BUILDING NEWS.

SIR,—As an outsider, I think Mr. Oliver has not been generously treated by the corporation and its officials in the above matter, and I should not have troubled you, had I not seen that Mr. Fowler has appealed to a wider circle through your columns. For the information of your readers, I trust you will afford me a short space for a brief explanation. In 1875, or about two years before Mr. Fowler came to the town, the corporation proposed erecting a Free Library over the shops and buildings of the vegetable market. This scheme provoked a great amount of opposition, as the site was considered most unsuitable; however, it was contended that another could not be obtained equally advantageous. Things remained in a kind of deadlock until June, 1876, when Mr. Oliver proposed through the Press to amalgamate the Mechanics' Institute and Free Library, and prepared sketches and a perspective to explain his ideas.

Mr. Oliver was thereupon roundly abused by the secretaries and officials of the Mechanics' Institute, and by the supporters of the vegetable-market site; but the conviction at last became general that his suggestion solved the difficulty.

The corporation pocketed the hint, went to Parliament for compulsory powers to purchase, obtained at length a basis of settlement with the trustees of the Mechanics' Institute, and adopted this scheme. About a year after Mr. Oliver had

prepared his sketches, Mr. Fowler was appointed Borough Engineer, and in that capacity had to carry out the building of the Free Library.

With Mr. Oliver's ideas as a basis, our new borough engineer prepared his plans.

Upon a portion of the ground adjoining the Mechanics' Institute stands one of the guard towers of Mediaeval Newcastle.

This tower, which bore the brunt of many a savage onslaught in olden days, and which has been handed down to us in good preservation, is now to be swept away by our spick and span new engineer, who declares it to be a sham and a delusion, and the arched stone of which, he says, is a mere modernism.

This proposed act of vandalism has evoked an opposition ten times more bitter than that called forth by the original proposal to build over the vegetable market. The Press for weeks teemed with protests from every class of townsmen and from many representatives of old county families in both Northumberland and Durham. In public meeting a large majority condemned the outrage, and in the Council an influential and large number of councillors followed suit.

Mr. Oliver, when he built the Mechanics' Institute some years since, left the old Carliol Tower intact, and in his sketches for the free library, still proposed that it should remain. Objecting, as an old townsman, to see the landmarks unnecessarily swept away, he appeared before the Government Commissioner to oppose Mr. Fowler's scheme. His opposition has apparently made Mr. Fowler "exceedingly wrath," and he has, through your columns, rushed into print, and accused Mr. Oliver of making wilfully false statements, and preparing plans to obtain public patronage. Considering that Mr. Oliver has been in practice here for thirty years, that his father before him was for many years an architect and surveyor in the town, that Mr. Oliver prepared his plans for the free library before Mr. Fowler was known or thought of here; and further, that Mr. Oliver's ideas have been adopted without thanks or acknowledgment of any description; one would have thought that Mr. Fowler might have discovered some other motive than deceit and toadyism for Mr. Oliver's public-spirited conduct in this matter.

For myself, and a large number of friends interested in the preservation of the few remnants of old Newcastle still remaining, I beg, through your columns, to offer Mr. Oliver our thanks for his exertions to stay the Vandal's hand.—I am, &c., JOHN STOREY.

Studio, 7, Pilgrim-street, Newcastle-on-Tyne, May 27th, 1879.

CREOSOTING TIMBER.

SIR,—The correspondence on this subject must be very interesting to all connected with engineering works, and is likewise a very important one, and although Mr. Walker would appear to have his doubts about it, railway companies certainly believe in its efficiency; and I notice that the Mersey Docks and Harbour Board are now actually advertising for tenders for 43,000 cubic feet of Baltic red-wood sleepers, to be thoroughly injected with creosote on Bethell's process. Mr. Walker says, in speaking of the timber which failed, the heart was rotten; therefore, to my mind, no creosote had been there, or it could not have rotted; and I should like Mr. Walker to kindly answer me this question:—If, after the vacuum pump had exhausted all the air and sap from the timber, the oil was forced in, what filled the space about the heart? I should like to have Mr. Walker's opinion. The only conclusion I can arrive at is that the timber in question must have been simply immersed in a tank and not properly creosoted at all.

I have been indebted to the BUILDING NEWS for information at various times, and I must acknowledge that I have especially derived much profit by papers published by you, which have been read before the Civil and Mechanical Engineers' Society, and also the Society of Telegraph Engineers. Could not some of the authors of these papers give us their opinions and experience?

I think the jurymen, in the case of this post failing, ought to have taken the opinion of some expert in the creosoting process. When you consider the many thousand pounds spent annually on our railways in preserving these sleepers, it will be seen to be a matter of grave importance to the shareholders.—I am, &c., T. JACKSON.

CREOSOTED TIMBER.

SIR,—Please allow me to ask two questions on the above subject.

1st. Will Mr. Walker state if he noticed any odour of creosote in the decayed portion, because if it had been there once the smell of the creosote oil would be there for ever. Also, what did the broken timber weigh per cubic foot? which would tell us how much oil had been taken up.

2nd. Will Mr. Brain explain how the air and sap are extracted, and why the heart wood does not take up any of the injected oil? As I take it, if there is no creosote at the heart, and the outside is encased with the injected matter, it seems to me it must ferment.

Some years ago you had some able articles in the BUILDING NEWS on preservation of timber; will the author give your readers his opinion?—I am, &c., J. SOMERS.

20, Montpelier-street, Highbury, N.

Intercommunication.

QUESTIONS.

[5779].—**Shores.**—Can any more diligent reader refer me to back numbers in which the theory and practice of raking and other shores has been exhaustively treated? It is a subject which would quite suit Henry Ambrose, but I cannot find that he has touched upon it. Does the rule of thumb alone regulate these important constructions, and, if so, what does it prescribe?—F. JONES.

[5780].—**Concrete.**—I am using concrete composed of the following materials (by measure):—1 of cement, 2 of scientific lime, 15 of broken brick, and 5 of sand. Can any reader say from experience if such a mixture will make a good concrete foundation? The contractor says the cement and scientific lime will not permanently amalgamate, and that the lime will cause the cement to "come again."—G. S. W. J. C.

[5781].—**Acoustics.**—What is the best and most approved modern work on the construction of theatres and lecture halls, especially containing directions relative to sound? Please state name of publisher and price.—ARCHITECT.

[5782].—**Right of Access.**—Attached to A's front wall are certain steps which formerly led to a first floor of C's, the use of both of which is now discontinued. Can C take away the steps and erect something else in their place (A owning the land in front and back)? Does C lose the right of the ground the steps stood upon if he removes them? Can C regain the ground by replacing the steps after an absence of several months?—X. Y.

[5783].—**Purification of Sewage.**—I am extremely obliged to Mr. Jackson for his replies to my queries. Would he now, or any other correspondent, say if the Local Government Board can grant special authority for directly turning a village sewage into the adjoining stream, which is not used for domestic use, or can the local sanitary authority do so by their own authority? I will be much obliged by any information in this matter as the "Tivers Pollution Act" most distinctly prohibits such a proceeding without, so far as I can see, any exceptional or saving rights being mentioned. I may add I know of a district being drained at the present time, and the outfall sewer is directly turned into the village stream. I would like to know on what authority this is being done or can be done. It seems to me absurd to ask a small provincial place of, say, 4,000 inhabitants to construct filters, &c., &c., when irrigation is all but impossible, and, at any rate, very costly. Probably Mr. Jackson will again oblige me.—A LOCAL SERVEYOR.

[5784].—**Discharge of Water.**—What will be the quantity of water discharged per hour from a pipe 20in. diameter and 1,800ft. in length, the head being 250ft. above the delivery? Rule wanted.—PURN.

[5785].—**Building Stone.**—Can any reader give me the name of the stone with which St. George's Church, Birmingham, is faced? A reply will greatly oblige.—J. C.

REPLIES.

[5759].—**Timber Verandah.**—Before "Axiom" writes in the dogmatic way he has done in this matter, he had better look at some examples of oak verandahs. Has he ever erected one? Probably he has not, or he would have discovered that a study of woods can only be made from constructed examples. Let him ask any builder which stands the best in out-of-door work—good red pine timber or oak. No one doubts the strength or durability of sound oak, but that generally used is knotty, apt to warp and split, while the red pine is durable, straight, and can be worked with greater facility.—G. H. G.

[5773].—**Lime.**—Rich limes will, with the addition of water, after having been slaked, become from 3½ to 4 times their original bulk, and when slaked they will hiss and produce hot vapour, and fall to powder instantly. Poor limes do not so much expand in slaking nor by the addition of water, and will otherwise slake as the rich limes, excepting they will require 5 or 6 minutes. Hydraulic limes will set under water in from 4 days to 12 months. Quick lime is lime after it has been burnt in the kiln, and thereby had the acid driven off. It is also called pure lime. Chalk lime is pure lime, and if made into mortar will absorb carbonic acid, and thereby become soft, having a great affinity for water. Poor limes contain no alumina, but insoluble silica. Limes more or less hydraulic contain alumina and soluble silica, and these, as well as the poor limes, expand in setting. The test for a sample of lime will be to slake a little, and add sand and make it into mortar, and fill a very small wooden box with same and put it under the influence of heat, and if it presently shrinks it will not do, as it would shrink on the works. A

good method to adopt is to have lime containing about 10 per cent., of silica. Various tests by muriatic acid, &c., can be applied to ascertain qualities.—HENRY AMAROSE.

[5775.]—**Heating Kiln.**—How would the following method answer? Line the shed throughout with tin as a reflector of heat, and the floor to be rendered a non-absorber of heat by being covered, say, with tin of saw-dust, and then from the lowest level have diminishing tin hot-air pipes fixed at an unvarying inclination of, say, 1ft. in 3ft., and this would carry some right round the building; they might be placed one above the other, several inches apart, and two or three tiers of them, commencing, say, at perhaps 8in. diameter, and diminishing, say, to 3, and their small end at length carried out of the pipe under the roof; and in all cases every precaution must be taken to prevent their getting near any timber in the construction of the building for fear of ignition, and the fire or furnace to heat them must be below the level of the lowest part of pipe in each case, and the most abundant precaution should be exercised to prevent the barest possibility of the flame from the fire entering the hot-air pipes; this may be effected by several divisions of wire gauze, and by dampers and other means, and above all by a proper arrangement generally. I should think a radiating reflective hopper would be the best means to convey the heat into the pipe, but there must also be an efficacious means of supply in abundance of cold air to feed the hopper, or, better still, to feed the fire, taking care that the fire does not also feed the hot-air flue with smoke and flame. The tin pipes could, I think, be so turned at the edges or seams by being beaten together on a mould as to render the dependence on the solder of little importance, and light iron suspension chains might be used to fix them, or light iron brackets if next to the wall, diminishing the sizes of the pipes gradually, which must be accurately calculated and worked to, and if adopted would be likely to cause a very strong draught, and thereby retain the hot air as it passed through the pipe, and when it passed out of the pipe it would then get dispersed in the building. It should be clearly understood that heated air becomes lighter and consequently ascends, and if any dip should exist in a pipe the circulation of the air would most probably stop. The preceding is only suggestive, as I have not tried it nor known it to be tried, but a cheap experiment on a small scale might be made to test its probability of success or otherwise.—HENRY AMAROSE.

[5775.]—**Heating Kiln.**—In answer to "W. and Co.," I can tell them of what I consider the best and cheapest mode of heating their kiln. A friend of mine has one heated by a small tube hot-water apparatus by Hearn & Co., Liverpool; the heat given is 190°, and it dries 2 tons of a material containing 58 per cent. of moisture every twenty-four hours. My friend assures me of its economy and efficiency. The furnace of brick is built below level of drying plate, the fire bars are of piping and are full of water; the pipes run from furnace round the kiln and under the plate. The water is continually being re-heated, and the power of the apparatus is surprising. I have been told that this apparatus will give any temperature up to 550 degrees, and, judging the ease with which my friend gets 190°, I do not doubt but what they can obtain 600°.—J. A. BUCK.

[5777.]—**Drawing Ink.**—T. Drew can obtain the ink mentioned by Mr. Neale by applying to the inventor, Mr. Featherstone, Trumps-green, Virginia Water, not Chertsey, as stated by Mr. Neale.—E. C. P.

LEGAL INTELLIGENCE.

BURNING BALLAST.—A builder named Charles Kellon, of Coleridge-villas, Kilburn, was summoned at the Marylebone Police-court on Tuesday, for burning ballast close to dwelling-houses, contrary to an order of the Willesden Local Board of Health. Medical evidence having been called to show that the practice of burning ballast as the defendant had done was injurious to health, he was ordered to pay seven guineas costs, and obey the injunction of the local board.

ENGINEER'S OR ARCHITECT'S POWER TO DETERMINE CONTRACT.—If High Court of Justice, Chancery Division, May 23. Before the Master of the Rolls. *Kassell v. the Castleford Local Board.* This was an action arising out of the bankruptcy of one of the contractors for the erection of a new market-place at Castleford. Two brothers, John and Thomas Kassell respectively, contracted to do the joinery and bricklaying work, but on May 3rd last John became bankrupt. The terms of contract with the board were that if the engineer to the board on inspecting the works found that they were progressing unsatisfactorily, or at insufficient speed, the board, on giving two days' notice, were to be at liberty to take possession of the works. When John Kassell became bankrupt the engineer inspected the works accordingly, and finding that they were not progressing satisfactorily, reported to a meeting of the board, who adopted a resolution, and gave the contractors notice of their intention to take possession, which was subsequently done. An injunction was now moved for to prevent the board from remaining in possession of the property, and asking that Thomas Kassell might be allowed to continue working, according to the original contract, as he alleged that the delay was no fault of his, but was caused by the brickwork being incomplete, which had prevented his going on. It was also contended that the clause contained the word "contractor," which could not mean all the contractors. His lordship in delivering judgment, said there was really no case at all. The contract was in the usual form of such contracts, by which the builder or contractor was practically at the mercy of the engineer or architect. The words

of the contract were "should it appear to the engineer that the works are not proceeding satisfactorily, or that they are not being executed according to the terms of the specification" the board could then take possession. "Should it appear to the engineer." Therefore, all he had to ascertain was whether the works did appear unsatisfactory to the engineer, and he had no reason for taking into consideration the opinion of other people. The engineer on inspecting the works was dissatisfied with them; and, moreover, reported that they were not "proceeding" at all, and if that opinion was given *bona fide*, and there was no pretence for saying it was not, that would be evidence to the local board of a kind calculated to induce them to take possession of the works. It was not suggested that the engineer was desirous of doing anything but the performance of his duty in the ordinary way, and even if he were wrong, the contract said if it "appeared" to the engineer. His certificate was to this effect: "I beg to call the attention of the board to the fact that the works under contracts 1 and 2 are not progressing satisfactorily, and I ask you to give notice to the contractors, as rendered necessary under the clause." That notice was given, and he should have thought it would have been enough. Then there was a special meeting of the board at which the subject was discussed, and Mr. Wheeler, the engineer, stated that he considered the position of affairs demanded the interposition of the board, and accordingly they passed a resolution, and gave notice of their intention to take possession of the works. Under these circumstances, the engineer having stated his opinion that the works were not progressing favourably, and the board having acted in accordance with his report, he was of opinion that the appellant had no right to ask the Court to make another contract for him. He should refuse the motion, with costs.

Our Office Table.

THE Parkes Museum of Hygiene, temporarily located at University College, of which the Queen is patron, will be opened to the public on and after the 1st of July next. The opening ceremony will take place on Saturday, June 28th, when a meeting will be held in the Botanical Theatre, under the presidency of the Secretary of State for the Home Department. Although the Museum is yet quite in its infancy, it contains a very valuable collection of objects and apparatus relating to every branch of sanitary science. As the only institution of its kind existing in London it will supply a very great want to those in need of facilities for obtaining a practical knowledge of sanitary matters, and professional men, employers of labour, manufacturers, artisans, and other persons, both men and women, will be able to study at their leisure those subjects in connection with sanitary arrangements in which they may be interested, and the benefits of the museum will therefore be extended to all classes of the community. The executive committee—of which Sir William Jenner is chairman—rely on voluntary subscriptions for the support of the new institution under their charge. Of the subscriptions already received they have invested £600 as the nucleus of an endowment fund. In all, something under £1,100 has been subscribed in sums varying from £1 to £50, the latter sum having been given by Her Majesty the Queen. Additional subscriptions are much needed. Manufacturers and others desiring to place articles in the museum will be supplied with the necessary forms on application, by letter, to the curator, Mr. Mark H. Judge, University College, Gower-street, W.C.

THE *Preston Chronicle* tells the following somewhat misty story with reference to the existing masons' strike at Blackburn:—A contractor was said to have sent on Tuesday (in last week) several loads of stone from his quarry to the yard of the Grapes Inn, Northgate, as a gift to the operative masons on strike; but the conditions were that the men should dress the stone and sell it, and spend the proceeds in drink at the Grapes Inn. The men hold their club meetings at this house. Another rumour was that the stone was to be dressed and returned to the sender, when he would pay the men for their work, saying that if they would not go to their work he would send work to them. Whichever of the tales be the correct one, the men set to work about noon and dressed the stone in the yard outside the inn, beer meanwhile being liberally supplied to them. A captain was appointed, and one of the rules laid down amongst

them was that any man who pulled his coat off should be discharged forthwith. Very soon the stone was sold—so, at least, it was stated—and before five o'clock no less than 11 gallons of beer had been served out.

THE dangers of imperfectly-protected glazed well-openings were exemplified at an inquest held on Tuesday week on the body of a maid-servant employed at 200, Queen's-gate, Kensington. On the top floor of this new residence is a landing with a skylight above, and in the floor of this landing are placed three sheets of glass, lighting the staircase and landing below. The glazed surface was surrounded by a rail 8ft. high. A fortnight since the deceased and another servant were throwing towels at each other on the landing, when one fell on the glass; deceased sprang over the railing to get it, the centre sheet of glass gave way, and the girl fell a depth of 60ft. or 70ft. into the hall, the marble slab paving being broken into pieces by the force of the impact. The coroner, Dr. Diplock, remarked that the accident would not have occurred if the glass had been of sufficient thickness; but builders put in inferior material, and the law did not touch them. A correspondent asks whether similar glass flooring is not being placed in other mansions now building in Kensington, and suggests that a low railing placed around opaque glazing is an insufficient guard where young and thoughtless persons have the opportunity of playing on the landings.

THE Turners' Company have announced their intention of again awarding the freedom of the company, silver medals, &c., to the workmen who send in the best specimens of hand-turning in hard or soft woods, stone, iron, steel, brass, or gun-metal. The specimens may be the work either of master, journeyman, or apprentice of the trade in England, and must be delivered at the Mansion House during the week ending October 4, where they will be publicly exhibited on the Tuesday, Wednesday, and Thursday following, the Lord Mayor distributing the prizes on the last day. Lady Burdett-Coutts, who is a member of the company, has given £50 towards the prizes, a like sum to be contributed by the Court of the Company. Bronze medals and certificates of merit will also be awarded.

THE building which once formed St. Andrew's College, Harrow Weald—an institution set on foot by the late Rev. Edward Monro—was, according to the *Guardian*, a few weeks ago put up for sale by auction, after remaining unused, except by casual tenants, since its abandonment some twenty-five years ago. The hall, designed by Hardwicke, and the chapel and library, designed by Butterfield, have been pulled down, and the materials are being used for converting what were the dormitories into a row of cottages. Strange to say, since its abandonment no owner has come forward, and the site is now the property of the village policeman, who took up his abode in a portion of it some fourteen years ago, and now finds himself its owner, under a recent Act of Parliament, by virtue of more than twelve years' undisturbed possession. The stained-glass windows of the library, which were manufactured on the premises by certain of the students, have been preserved for the present, the material being useless for the purpose of cottage construction; a portion of the glass has been purchased by one of the former students, who, in paying a solitary visit last week to Harrow Weald for old association's sake, found the buildings in course of demolition.

WE are informed that the vicar of Arundel, the Rev. George Arbuthnot, left England after the trial for a tour in the East, and it is doubtful when he may receive intelligence of the judgment in the Arundel cause. Any decision as to appealing against that judgment cannot be made until his return. But it is not probable that the risk of further legal proceedings will be incurred unless it appears that substantial help be expected from Churchmen generally towards the prosecution of a suit which involves principles and consequences very far beyond the sphere of the church at Arundel. We think this help, however, would be forthcoming, and we trust it will be invoked. Architects generally have but one opinion about the matter, however their opinions may have been misrepresented by utterances which have been made under Roman Catholic inspiration.

At the twenty-fifth and concluding meeting of the Institution of Civil Engineers, on Tuesday, Mr. Bateman, F.R.S.S., L. and E., the president, stated that during the session just terminated 68 associates had been transferred to the class of members; 60 members and 180 associates, of whom 40 were previously students, had been elected, and 153 students had been admitted. Since the same date last year there had been a net increase of 84 members, 59 associates, 74 students, and 1 honorary member. These several classes now numbered 1,156, 1,829, 598, and 17 respectively—together 3,600, as against 3,382 twelve months ago, being an increase at the rate of $6\frac{1}{2}$ per cent.

The Bradford Art Gallery and Museum was formally opened to the public on Wednesday. The room in which the pictures are exhibited is a very suitable one. The floor of the room is occupied with cases, in which are exhibited a number of artistic objects, articles of curiosity, and specimens of art-pottery, jewellery, &c., contributed by the South Kensington Museum and one or two prominent local tradesmen. There are in all about 300 works exhibited. The work shown have been the choicest examples of many exhibitions, and have been selected from time to time by local art patrons. The works almost entirely belong to the modern English school, and include examples by D. MacIach, Sir Edwin Landseer, J. Pettie, H. Stacy Marks, T. Faed, Clarkson Stanfield, the Linnells, R. Ansdell, Vicat Cole, H. O'Neil, E. M. Ward, J. Sant, L. J. Pott, Alma Tadema, C. W. Cope, S. Prout, J. L. Tissot, R. Beavis, G. Smith, S. L. Fildes, A. Elmore, Erskine Nicol, F. Goodall, J. McWhirter, &c. As regards foreign art, the display is but meagre. Rosa Bonheur is represented by a characteristic cattle piece; Meissonier by one of his studies of the last century; Verboekhoven by one or two of his paintings of sheep; and Duverger by a few incidents of foreign life and sentiment rich in local colour.

The local authorities of Ipswich appear to be singularly unfortunate in their recent building operations. A few weeks since we referred to the serious defects which are revealing themselves in the new town hall, and from the report of the last meeting of the Ipswich School Board we see that that body also is having evidences of bad workmanship brought before them in the schools built about six years ago, under the superintendence and from the designs of their late architect. Mr. Binyon, the present architect to the School Board, reported that at the Trinity-street Schools the water got into the roof through the lead gutters, the lead was not properly turned over nor heavy enough, and did not extend high enough under the slates; the eaves gutter of the cloak-room was blocked; the lead flashing behind the gable wanted retrenching and pointing, as did the ridge cresting, and other repairs were necessary. At other schools in the Wherstead-road the state of the bellcote allowed rain to drive into the infant school-room, the fastenings to the lantern windows and skylights were all defective, and the slates were loose, the latter being due to the fact that wrought-iron nails were used instead of zinc nails, as specified.

CHIPS.

A new flagstaff, erected last week on the tower of Shelton Church, Staffordshire, deserves notice on account of its being, it is said, the largest in England. The pole is the trunk of a Russian larch, 65 feet high, and the flag is 21 feet by 13 feet.

Beacon Crag, a new villa residence at Porthleven, has just been completed from the designs of Mr. J. Trounson, architect, of Penzance.

The Eccles and Barton Local Board have agreed to build a new Town Hall, the cost not to exceed £5,000, exclusive of the furnishing and cost of land. There is to be a public room capable of seating 1,000 persons. The plans are expected to be ready in a month.

The memorial stone of a new Sunday-school, in connection with the Fuller Chapel, Gold-street, Kettering, was laid on Monday week. The chief material used will be red brick, with native iron stone for the plinths of the pillars, Ballingdon bricks for the arches, &c., and red Mansfield bricks for dressings. The total cost is expected to reach £2,600. The architects are Messrs. Joseph Gale and J. Alfred Gotch, Long-lane, Bermondsey; and the contractor, Mr. A. J. Margetts, of Kettering.

New school buildings in connection with St. Cuthbert's Parish Church, Edinburgh, are at present in course of erection. The block has a frontage of 92 feet, and is designed in the old Scotch style. The total cost will be about £2,000. The building has been erected from plans furnished by Messrs. McGibbon and Ross.

The high price realised for 13 freehold houses in the Camberwell-road, at their recent sale by Messrs. Rushworth, Abbott, and Rushworth, on Tuesday, may be of some interest. After considerable competition the property was sold for £17,000, i.e., about 28 years' purchase on the rental, which would pay about $3\frac{1}{2}$ per cent. only.

At Wandsworth Police-court, on Wednesday week, W. Gander, a builder, was fined 40s. and costs for erecting a building without giving proper notice.

The statement that Mr. De Keyser had accepted a tender for building on the vacant ground adjoining the Royal Hotel, Victoria Embankment, is contradicted.

The memorial stones of a new Wesleyan Chapel have been laid at Stechford, a rapidly-growing suburb of Birmingham. The building is of red bricks, and will seat 350 persons. The cost will be £1,500. Mr. George Ingall is the architect, and Mr. William Lee, of Aston, the builder.

The statue of the Right Hon. Sotheron Estcourt, the most prominent feature of the memorial of that gentleman now being erected in the market-place of Devizes, was placed on its pedestal on Monday week. Mr. Nicholls was the sculptor. The basin and drinking-troughs of the fountain are being set in position by the contractor, Mr. Wheeler.

New board schools are about to be erected at Fleetwood, from the designs of Mr. J. A. Seward, of Preston.

From the reply given by the chairman of the City Lands Committee, at the Court of Common Council of the City on Thursday week, it appears that no decision has yet been come to as to the exact spot on which Temple Bar will be re-erected, but the ancient boundary of the City will be marked in some permanent manner.

The memorial stone of a new Baptist Chapel was laid at Newbridge-on-Wye on Thursday, the 22nd. The architect is Mr. H. Thomas, of Cwmtyrch, and the builder Mr. Howells, of Ystradgynale.

The statue of the late Sir John Gray, M.P., which has been executed by Mr. Farrell, R.I.A., was placed on its pedestal at the crossing of Abbey and Lower Sackville-streets, Dublin, on Monday. It is to be formally unveiled on the 24th June.

Towards the close of last year a class of Art and Design was formed in connection with the Literary Institution, Blandford, and about 70 pupils have met in the Freemasons' Hall, under the instruction of Mr. W. E. Brennan. On Wednesday and Thursday last the works executed were publicly exhibited.

The parish church of Gwyddelwern, near Corwen, Merionethshire, is about to be restored, from designs prepared by Mr. Kennedy.

Recently a great many fragments of cinerary urns, such as were used by the Romans for the preservation of the products of cremation, have been discovered at Runham-Vauxhall, near the foot of the suspension-bridge connecting the hamlet with Great Yarmouth; and at the same place, on the 14th inst., a copper coin of Augustus Caesar, upwards of an inch in diameter, and in good preservation, was picked up.

On Saturday afternoon the corner-stone of a new Wesleyan day and Sunday-school was laid at Kersley. The plans have been prepared by Mr. Thomas Ormrod, architect, of Town Hall-square, Bolton, and the work is being carried out under his direction by Mr. Jno. Taylor, joiner and builder, Farnworth. The cost of the building, according to present contract, will be about £970, but the heating, lighting, and furnishing, also boundary walls, outbuildings, drainage, &c., will, it is estimated, bring the total expenditure to upwards of £1,300.

On Tuesday Major Tulloch held a Local Government Board inquiry respecting an application by the Local Board of Cirencester to borrow £1,300 for works of drainage, one object being to relieve the town from floods caused by the overflowing of the Chur. The clerk to the Board and Mr. R. B. Grantham, the engineer, explained the scheme, and mentioned that tenders amounting to £8,047 10s. 10d. had just been accepted from one contractor for the sewerage of the town.

The Northern Lighthouse Board have accepted the tender of Messrs. Morrison for the erection of a lighthouse on Langness, Isle of Man.

The Town Council of Great Yarmouth have had under consideration alternative plans for laying out their land to the north of the workhouse as building sites prepared by Mr. Bly and by the town surveyor, and decided on Tuesday week to adopt the scheme of the latter gentleman.

The death is announced of Mr. Cavell, for many years an alderman and J.P., for Deal. Born in 1804, Mr. Cavell was educated as a civil engineer, and subsequently joined the Royal Engineers. In 1841, he was engaged in superintending the construction of new barracks, an English church and other Government buildings, on Newcastle Mountain, in the island of Jamaica. In 1848 he returned to Dublin, and was appointed surveyor of barracks and overseer of military works, and subsequently was specially selected to superintend the erection of a breakwater at Carrickfergus. He retired from the service in 1858, and has since resided at Deal.

Roofing Felts.—F. Braby & Co.

INODOROUS, SARKING, SHEATHING, AND HAIR FELTS KEPT ALWAYS IN STOCK. MANUFACTURERS OF PERFORATED ZINC, PERFORATED COPPER, AND PERFORATED IRON IN VARIOUS DESIGNS AND GAUGES.

Wrought Iron Tanks.—F. Braby & Co.

PAINTED AND GALVANISED, OF IMPROVED MANUFACTURE

Corrugated Iron.—F. Braby & Co.

GALVANISED AND BLACK IN ALL GAUGES, KEPT IN STOCK. ZINC WORK OF ALL KINDS.

FITZROY WORKS, 356 TO 369, EUSTON ROAD, LONDON.
HATTON GARDEN, LIVERPOOL. GREAT CLYDE STREET, GLASGOW. AND AT CYPRUS.

The new line between Cliftonville and Preston, near Brighton, has been completed, and was officially inspected on Friday by Colonel Yolland, of the Board of Trade. The line has been constructed for the London, Brighton, and South Coast Railway Company, by Mr. Firbank, contractor, under the superintendence and from the designs of Mr. Bannister, the Company's engineer.

Five of the metropolitan bridges over the Thames, Lambeth, Vauxhall, Chelsea, Albert, and Battersea, were opened free from toll on Saturday afternoon, by the Prince and Princess of Wales. The Wandsworth, Putney, and Hammersmith bridges remain to be freed.

Piel Bar, at the entrance to Barrow-in-Furness Harbour, has been so far removed, that the channel steamers can now gain access at all states of the tide.

A new endowed school for girls has been opened at Ilminster, and a boys' school is in course of erection opposite this.

Some time since an oak-tree was found under the bed of the river Tone during excavations, and was presented by Alderman Taylor to the Taunton corporation, who resolved to have it made it into a civic chair. The work was entrusted to Mr. Arthur Stevens, of the same town, who has just completed it. The design is Perpendicular Gothic in style, the front part of the chair resting on lions' feet, bearing massive canted and moulded pillars on which stand carved lions supporting shields. The sides are arched, and within them are richly-carved allegorical shields, representing Agriculture and Commerce on one side, and Science and Art on the other. The back is also arched, and rests on columns with carved capitals supported by buttresses, the corporation seal being cut in the centre of the back. The chair is upholstered in olive-green morocco.

The restoration committee appointed by the vestry of Billericay, South Essex, to consider what steps should be taken for restoring the church tower, have adopted the report and suggestions of Mr. J. E. K. Cutts, of Southampton-street, Strand, provided that the work can be carried out so as to preserve the original character of the building. The steeple is a quaint 16th-Century structure of red brick, built into the street-front of a more modern brick chapel of ease; the pinnacles and battlements have long been in a crumbling and dilapidated condition.

The foundation-stone of a new Cistercian monastery was laid at Mount St. Joseph, Roscrea, Connaught, on Thursday se'night, the 22nd inst. The estate comprises 500 Irish acres, and, together with the mansion upon it, has been presented to the community by Count Moore, M.P., at a cost of £10,000. The house is being altered to serve as a guest-house, and the several monastic buildings are to be erected as funds permit. The church now in course of erection will be Early English in style, and will be 210ft. in the length and 60ft. across nave and aisles, both in the clear. Over the southern transept will be a bell-tower; the walls will be of ashlar work, the columns of limestone from Roscommon, and the arches of sandstone. The architect is Mr. W. A. Beardwood, of Manchester, and late of Dublin.

MEETINGS FOR THE ENSUING WEEK.

WEDNESDAY.—British Archeological Association. Papers on "Further Discoveries at Lincoln," by the Rev. J. M. Mayhew; "The Harness Company of the City of London," by C. H. Compton, and "The Course of the Wansleyke, near Bath," by Mr. J. T. Irvine, 8 p.m.

THURSDAY.—Society for the Fine Arts.

HELLIWELL'S Patented NEW SYSTEM

IMPERISHABLE GLAZING WITHOUT PUTTY. All Woodwork is covered, and no outside painting is required. Old Roofs Re-glazed. Any one can repair or take in pieces.

T. W. HELLIWELL, Brighouse, Yorkshire; or, 19, Parliament-street, London.—[ADVT.]

Holloway's Ointment may be relied upon in cases inflammation or irritation of the internal mucous membrane. When it is diligently rubbed upon the Back and Chest, it relieves shortness of breath, fluttering of the heart, stitch in the side, cures colds, asthma, bronchitis, and protects the delicate against consumption.—ADVT.

Trade News.

WAGES MOVEMENT.

OXFORD.—The operative masons of Oxford received six month's notice in November last, of a reduction of wages amounting to 4s. 5d. per week,

with other alterations in the rules. They have addressed a letter to the chairman of the Master Builders' Association, stating that in their opinion the present and immediate future state of the trade in Oxford does not justify the suggested alterations, and requesting an interview.

Douling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to

CHARLES TRASK,

Norton-sub-Hamdon, Ilminster, Somerset.

Agent: Mr. E. CHICKMAY, 4, Agar-street, London, W.C. —[ADVT.]

TENDERS.

ABINGDON.—For the restoration of the old Council Chamber for the Mayor and Corporation of Abingdon, Berks. Messrs. Morris and Stallwood, architects, Reading:—

Wyatt, G., and Son...	£1,331 11 4
Wheeler, Brothers...	1,300 0 0
Silver, R., and Sons (accepted)...	1,184 0 0

BAONALL HALL ESTATE.—For conversion of existing buildings into five dwellings, for John Keats, Esq. Mr. W. Larnier Sugden, architect. Quantities supplied:—

Grosvenor, J., Tunstall...	£750 0 0
Matthews, Bros., Endon...	737 0 0
Heath, J., Endon...	690 0 0
Nadin, J., Leek...	599 15 0
Green and Hall, Leek...	595 0 0
Leek, W., Hanley (accepted)...	485 0 0
Harding, J., Badley-green...	481 10 0
Bailey, P., (brickwork, &c., only)...	550 0 0
Knight, G., (brickwork, &c., only)...	460 0 0
Casey (plasterer)...	53 0 0
Hudson, Jas. (joinery)...	216 12 0
Hudson, Joseph (joinery)...	199 0 0
Wood, Bros., (joinery)...	169 0 0
Phillips, Edwin (plumbing, &c.)...	58 8 0
Johnson, T. (plumbing)...	50 0 0
Heath, Isaac (plumbing, &c.)...	48 1 0
Stevenson, H. (plumbing, &c.)...	40 0 0

BIRMINGHAM.—For a new church at Nuthurst, near Knowle. Mr. John Cotton, architect, Birmingham. Quantities supplied:—

Brazier and Weaver...	£2,435 0 0
Davies, Brothers...	2,400 0 0
Wilson and Son...	2,390 0 0
Robinson...	2,322 0 0
Smallwood and Co....	2,226 0 0
Partridge...	2,170 0 0
Barnsley and Son (accepted)...	2,123 0 0
Inwood...	2,117 0 0

BRONSCROVE.—For alterations and additions to The Cedars, Blackwell, for Thos. Scott, Esq. Mr. John Cotton, architect, Birmingham. Quantities supplied:—

Mathews...	£1,821 0 0
Smith...	1,694 0 0
Brazier and Weaver (accepted)...	1,526 0 0
Thomas...	1,502 0 0

COLCHESTER.—For alterations and additions to the Essex and Colchester Hospital. Mr. T. H. Wyatt, architect. Quantities by Messrs. George Lansdowne and Harris:—

Dobson, Colchester (reduced estimate), accepted £5,550.

CLAPHAM.—For village club at Clapham, near Bedford, for James Howard, Esq. Mr. John Usher, architect:—

Potter...	£642 0 0
Lilley...	596 0 0
Foster...	576 0 0
Knight and Boston...	560 0 0
Adams...	550 0 0
Freshwater (accepted)...	539 0 0

DULWICH.—For villa residence, Overhill-road. Mr. Richard Peters, architect, Wool Exchange, Coleman-street, E.C.:—

Watson and Dennett (accepted) ... £4,356 0 0

DULWICH.—For alterations to Norse Lodge, Lordship-lane. Mr. Richard Peters, architect, Wool Exchange, Coleman-street, E.C.:—

Burchell... £420 0 0

Watson and Dennett (accepted) ... 330 0 0

DULWICH.—For alterations to Rose Bank stables, by conversion of same into dwelling-house. Mr. Richard Peters, architect, Wool Exchange, Coleman-street, E.C.:—

Watson and Dennett (accepted) ... £1,260 0 0

DULWICH.—For boundary fence, walls, and iron gates and railings, to villa residence. Mr. Richard Peters, architect, Wool Exchange, Coleman-street, E.C.:—

Watson and Dennett (accepted) ... £115 0 0

DEPTFORD.—For erecting cart lodges, stables, and disinfecting and destroying apparatus on the Board's premises in Knott-street, Deptford, for the Greenwich District Board of Works:—

Shrimpford...	£3,450 0 0
Scott and Sim...	2,535 0 0
Dover...	2,539 15 0

THE BUILDING NEWS.

LONDON, FRIDAY, JUNE 6, 1879.

ART IN COACH-BUILDING.

AN art presenting some points of relationship to architecture, that of coach-building, can claim as well an historical development nearly as extensive. The Company of Coach Makers, a very important and influential City guild, have held their annual exhibition this year at the Mansion-house, and through the enterprise of the master, Mr. Fredk. Chancellor, architect, and the wardens, the collection of drawings for the prizes possess more than the special interest that would in the ordinary course have been attached to them. The art element has been brought prominently into notice this year, for we have not merely the display of prize drawings of a mechanical and thoroughly technical description that rival the most elaborated geometrical drawings of architects and engineers, but a choice collection of old engravings, photographs, and works illustrative of the art of carriage-building from the earliest times, besides a number of prize drawings for freehand; and it is this feature that has lent to the exhibition a wider and more popular interest. The prizes of the Company are awarded for free-hand or mechanical drawings, and drawings of carriages to the scale of lin. to the foot, and these have been striven for by thirty competitors, among whose work we find a large proportion of excellent draughtmanship. Special prizes have also been given for competition among apprentices and young men under 22 years of age, and it is satisfactory to observe in this contest such really commendable efforts, evincing the value of the new art and technical classes that have been established. A former prize winner, Mr. J. P. Lake, wins the highest prize this year, the silver medal of the Company and £3 for drawings of a four-horse drag and a dress chariot. The report, with a just pride, observes "these drawings show that we have men in England quite competent to produce as good working drawings as those made in France and Russia, if the art is properly taught and encouraged." As mechanical samples showing a high knowledge of technical skill and projection, these drawings are all that can be desired, though the committee are wisely endeavouring to promote a higher art culture. Clever drawings are also exhibited by G. F. Budd, which arrived too late for a prize. For free-hand or mechanical drawing the 1st prize has been awarded to Mr. W. Farr, of Salisbury, a coach-trimmer and a winner of former prizes, for outlines of a pilaster, and some drawings from the antique; we note also a clear, careful drawing of a Greek vase and a scroll by Mr. G. Mundy, of Grantham, who wins the bronze medal. The figure and natural foliage afford excellent subjects for the student in this branch of art, and the ancient and foreign examples brought together show that modern carriage building would not lose by combining artistic with mechanical improvements.

The old drawings and engravings that are exhibited in the apartments at the Mansion House are particularly instructive, and we are glad to find the Company are making an effort to improve the taste of the designer in this department. The series of illustrations from the ancient war-chariot of the Roman or the Briton to the elaborate state carriages of the time of Elizabeth and Charles II., exhibit a continued artistic development; as in furniture, so in this art, structural form and elaborate carving and gilding seem to

have vied in the production of gorgeous, massive, and picturesque carriages, in which the leading artist's skill was sought. In the later style the body of the carriage, with canopied head, was suspended and the wheels richly turned, carved, and ornamented. We see examples of the highly decorated *caretta* or car, the chariottes of later times, the showy, gorgeously carved and gilded state carriages of Louis XIV. and Queen Anne. In the collection of photographs exhibited by the Company and Mr. G. A. Thrupp some particularly fine examples of state carriages are to be seen. We notice, for instance, in the Portuguese series a few superb carriages, with the bodies formed of straight sides, and with elaborate carved and fringed canopies suspended on leather straps; two backs of coaches of Kings Jean IV. and V. of Portugal show a profusion of bold carving of figures and grotesque scroll-work of the most artistic kind, the spokes of the wheels being carved in the most massive yet graceful manner. Another, lent by Mr. Thrupp, shows a coach of King Alphonso VI., about 1656. In one the car is open, sloped outwards at the top, covered by a canopy, and is suspended from a wide carriage of four wheels, all richly carved and gilt; it belongs to the 18th century. If not light or elegant these types are at least artistic, while it is a fact that architects, carvers, and painters of celebrity were employed in their production. We must not overlook a sumptuous coach built in 1713, on the occasion of signing the Peace of Utrecht, for the Duke D'Ossima—it is shown suspended upon leather braces; and a lighter-made one of the time of Louis XV., lent by Mr. Peters, the car of which is suspended, and has a canopied top in three segmental panels. The poles formed a principal feature in these carriages, and the leading-bar of Queen Anne's carriage, together with a piece of the carved and gilt scroll-work, are exhibited. The refined taste of Louis XV. is shown in several drawings; the massive and rectangular forms are changed for graceful curvilinear shapes, and the enrichment, while exceedingly chaste, is less gorgeous and profuse than that of the 17th century. The state carriage built by Godsal, of Long Acre, in 1785, for the coronation of the Queen, exhibits the style of more recent time, of which period several interesting drawings from designs by deceased carriage artists are to be seen. Many old engravings and books show the varied forms of vehicles in the 18th century. We may mention an old print by Vertue, illustrating the procession of charity-school children to St. Paul's upon July 7th, 1713, upon the occasion of a public thanksgiving for peace in Queen Anne's reign; this view shows the style of the carriages, the pages seated in front, and the running footboys, while the houses in the Strand are figured in the background.

The literature of coach-building is represented by a collection of choice books on the craft that occupies the Long Parlour. We open a curious old book, an account of the embassy from James II. to Pope Innocent XI. in 1685, and the state carriage used on the occasion by the Earl of Castlemaine, with its profuse carving, and the massive heavy gilded cars, are peculiarly interesting. Another old book is entitled, "A New Universal System of Inversible Carriages," dedicated by John March to the Prince of Wales. The engravings show designs for coaches with the bodies or cars swung in such a manner from the framework that they cannot be overturned. One postchaise is shown upset, its driver thrown forward, and its wheels completely turned up, while the page is handing out a young lady unhurt. We have only space to say the exhibition is worth a visit by all interested in the craft and by all artists; every conceivable kind of conveyance and style of

harness may be noted, from the earliest curicle, with its sliding bar or yoke, to the postchaise, and from the largest caravan to the latest-fashioned barouche or landau. As regards comfort, light construction, and handiwork, the modern carriage cannot be surpassed, if only a little more art could be bestowed upon it. To this end we welcome the exhibition, and think that much credit is due to Mr. Chancellor for having infused a higher tone into the exhibition, and for having, in conjunction with his committee, popularised the display by the present exhibition at the Mansion House.

APPLIED ORNAMENT.

RESEARCHES into the art of the Greeks and their predecessors, have proved that one great source of effect was obtained by superimposed materials to walls, &c. Thin hammered plates of metal, and inlays, were very common means of producing ornamentation. Müller, Wilkinson, Layard, and other authorities have alluded to the method of enriching sculpture, practised by the Egyptians, Assyrians, and Greeks, and some of the processes described are certainly very ingenious. Plates of gold, ivory, ebony, &c., were used to adorn the statues of the deities, and it is well known Phidias overlaid with ornaments and reliefs of those materials the statue and throne of the Olympian Zeus. In the remains of Greek buildings, as in the Parthenon, several of the surfaces have shown indications of the fixing of metal plates and ornaments, while colour on a species of gesso was by no means an uncommon mode of decorating the Egyptian and Assyrian buildings, as it was of the Greek temples. The Egyptians always applied a fine layer of white stucco or paint over stone, and even the obelisks were also treated in a similar manner. Upon this surface the colours were placed; these were mixed with water, and a little gum. Red, green, and blue were favourite colours. As a groundwork upon which to apply coloured decoration, gesso naturally leads us to ask why it is the modern architect has not done more with his plaster and cement. Stucco ornamentation, such as it was a few years ago, no one could wish to see reproduced, nor can we believe architectural taste will ever degenerate so far as to again bring into use cement architectural features to simulate stone or marble. But we are speaking now of internal stucco as a means of decoration in our walls and ceilings. Paper and various other coverings for walls have of late come into notice. Some of them are excellent; but, after all, no architect can say honestly there is anything to outdo in decorative effect the old plaster work of the 16th century, nor any art that can equal the style introduced in the early part of the 18th century. We may here profitably quote from a recent article in Messrs. Audsley's Dictionary, in which "gesso" is spoken of as a ground for decoration:

"Gesso of a very hard and durable nature was almost invariably used for the applied decorations on statues, columns, mouldings, and any small wall surfaces up to the 15th century, when, as M. Viollet le Duc informs us, a resinous composition was generally employed, which, from the action of heat and cold, has in almost every case peeled off. On this side of the Channel, however, gesso continued in use up to 1420, at which date the tomb of William de Colchester was erected in Westminster Abbey. It was originally decorated throughout with colours and gilding; and the apparel of the alb and the embroideries of the chasuble and maniple were applications in gesso. The modes of treating the gesso applications were uniformly simple, consisting of coatings laid on of a suitable thickness, and impressed with moulds or stamps of wood or metal; or of thin coatings laid upon the surface of the stone or woodwork, to which ornaments of gesso which had been previously prepared in shallow sunk moulds were attached while moist. The former process would produce patterns for the most part below the surface of the coating, the latter designs in relief."

It is known that during the Middle Ages wood mouldings and panels intended to be painted or gilded were often covered by a thin gesso, sometimes laid upon vellum. Messrs. Audsley quote Sir G. G. Scott's "Gleanings from Westminster Abbey," in which Queen Philippa's tomb is described to show that several kinds of application were employed, namely, the alabaster work and the gilt metal wings, besides a profusion of jewels, &c.

With the Romans applied decoration was carried to a great extreme. At Pompeii many fragments of opaque red and amethystine glass have been discovered embedded in the pavement, some combined with marble, and others entirely of glass mosaic. We have in these instances, therefore, something like an apology for the application of surface enrichment to our modern buildings, which architects have not been slow to avail themselves of in recent years. They have unfortunately, however, gone beyond the ancients; they have not stopped where they did, but have brought a rather well-merited rebuke upon themselves—that they merely copied with indiscriminate lavishness where their ancestors brought considerable skill and discernment to the task. If we examine any of the damascened work of the Orientals, we are impressed with a richness that does not oppress by its redundancy; the vases ornamented with metal plates of the Greeks and Egyptians, are even more moderate and tasteful, and these earlier works of the art of overlaying and enriching are as striking in their simplicity as the modern imitations are often coarse and feeble. Sir Gardner Wilkinson mentions the skill of the Egyptians in compounding metals and the methods adopted for varying the composition of bronze; and the vases and implements discovered at Thebes and other parts of Egypt, and seen in the British Museum, afford evidence of their taste in the employment of metal, either in plating or inlaying bronze.

To confine our attention to the Roman period, walls were overlaid with slabs of marble and mosaic, till they reached a degree of richness never surpassed. Works of art were encrusted with marble, gold, ivory, and even gems, and in the church of St. Sophia the incrustation reached its acme of perfection. In Venice the inlays of marbles are abundant, and one of the most pleasing modes of application consists in introducing circular and square panels or bands, with geometrical devices, into the wall-faces—a method to be seen in some of the Palazzi. Messrs. Audsley, in their excellent Dictionary, illustrate one of these from the Palazzo Dario. In London the atmosphere is not kindly to decorative inlays or enrichments of any sort, either externally or internally, as in both cases they suffer from a coating of soot and dust, as we can prove by numerous unsuccessful instances where tiles have been inserted. At the same time there is some hope for a glazed, externally-applied material that shall not deteriorate under an acid-laden atmosphere, and we can point to glazed stoneware, terra-cotta, and glass mosaic, as tried and excellent materials when artistically used.

Before suggesting the right mode of employment, let us consider some of the failures that have taken place in this kind of art. There has been some gross misapplication of materials in this manner. Cement upon brick is one of them. Whoever can look at any of our brick buildings with cement dressings, architraves, friezes, and decorative detail, once so common, without a feeling of disgust? The ground in this case is as precious as the applied cement. If marbles are the applied materials, we almost instinctively feel that the application is justifiable and honest, for then we give prominence to the more valuable; the same may be said of bronze upon stone, and ivory upon

wood. One of the most painful instances of the employment of one material upon another is when the applied material introduced in all the main architectural features is mechanically produced, and we cannot give a better example of our meaning than the terra-cotta inserted in the stock brickwork of the stations on the London, Chatham, and Dover Railway. These segment pointed arches with their coloured bricks and terra-cotta skew-backs and keystones, with a stamped trefoil in them, form a deplorable instance of introducing mechanically produced ornament in such positions. We always feel an interest in a plain, hand-worked brick arch, whether it be a flat-gauged arch in one of our old brick buildings, or an ornamental form of moulded brick; but directly we substitute for the hand-work the machine-made material, all art interest in it vanishes, for we know it can be reproduced *ad infinitum ad nauseam*. A plain plinth mould does not strike us as so glaring an instance of misapplication, and the practice only becomes unpleasing directly we pass the limit of bare utility, and try to save hand-work and skill by machine labour. Take one of our fine old plaster ceilings enriched by the modeller. Is it possible we could feel the pleasure and delight such a ceiling gives us if we knew the panels were ready-made and stuck on like the composition centre flowers to our ceilings? What gives their charm is the fact that they were designed for the ceiling and modelled by the hands of an artist, and that no reproductions of it can be found elsewhere. As soon as our manufacturers will cease keeping large stocks of ready-made designs, and will second the hands of the architect by working with him in the special requirements of certain buildings, the art of wall decoration will again take its place among the accessory arts of architecture.

PERSONAL AND PROFESSIONAL RECOLLECTIONS OF SIR GILBERT SCOTT.*

TRUE enough as it is that "lives of great men all remind us," we may, after some poor fashion at least, follow in the steps their bold strides have stamped more plainly on the path of duty, and hence, in this respect at least, our chief interest is in the record of their work in the world and their character as it knew them, yet we all long to learn more than this about men who are really worth remembering. And when, as happens now and then, one who has gone from us leaves behind him his own account of the early surroundings of a life in which not till long after his fellow-men learned to interest themselves, of the struggles and disappointments which came thickly together before the success of later life, and above all of the reasons for and causes of many actions of the writer which during his life we had puzzled ourselves in vain to account for, and perhaps ignorantly called in question, our interest is more than half mingled with gratitude for the privilege afforded us of a familiarity with the mind and inner life of the author, which few—possibly none—during his life could share. Such an interest is attached in an especial degree to the book before us. Sir Gilbert Scott was not only the foremost architect of his age; he was, as Dean Burgon says in his introduction to this record of Sir Gilbert's life, unquestionably the great art teacher of his generation, and standing in the light of the great art revival which the past forty years has witnessed, we turn with an eagerness unparalleled, except perhaps in the case of Pugin, to discover how in the midst of darkness the first gleams came upon the path of the student, who would then

have looked long around him in vain for any guide, save only the neglected monuments of lost knowledge which it was his after-mission to restore to their former splendour. It is perhaps hardly possible for art students of the present generation, with their ample opportunities of obtaining knowledge, fully to comprehend the enthusiasm and earnest love for English architecture which must have animated the mind of Sir Gilbert Scott at the commencement of his career, but none the less valuable will be the lessons his life affords of tireless industry and integrity of purpose, without which the most shining talents fail to effect much worth doing. Those amongst us who personally knew and valued the great church builder of the nineteenth century apart from his works' sake, will find in this unaffected history of his life much to remind them of the courtesy and simplicity which characterised it, and all will obtain information—and occasionally considerable amusement—from its pages.

The book, we learn from the preface, was designed originally only for the information of Sir Gilbert Scott's family, but as the work progressed its scope became enlarged, and in 1873 its author drew up directions for its publication after his decease, feeling it due to himself "that the statement of his professional life should go before the public in a fair and unprejudiced form; the more so as he had been one of the leading actors in the greatest architectural movement which has occurred since the Classic renaissance." The manuscript naturally enough contained much matter unsuitable for publication, which has been omitted under the editorship of Mr. G. Gilbert Scott, who has performed his work conscientiously and with tact, giving us just as much about his father's purely domestic concerns as the public had a right to know, and withholding nothing of more public and professional interest. The appendices, which contain an account of Sir Gilbert's death and funeral, together with Dean Stanley's sermon, and some papers on the subject of restoration referred to in the work, add completeness to the book, which is suitably introduced by Dean Burgon, except, perhaps, the last few sentences, which relate an incident which we can hardly help thinking might have been kept as private as must have been originally intended.

Sir Gilbert Scott was born at the Parsonage House at Gawcott, near Buckingham, on July 13, 1811. He was descended from the Scotts of Scott's Hall, in Kent, who left Scotland in the 13th century. His mother's family, from whom he derived his second name, were West Indians. His grandfather, the Rev. Thomas Scott, was the well-known Biblical commentator, and his father was the first perpetual curate of a church at Gawcott, which had been built by one John West, a retired lace-buyer, and which after it was built its founder had such great difficulty in getting consecrated that at last he sent word to the Bishop (of Lincoln) that if he would not consecrate the building it should be given to the Dissenters. Even for the time, the church appears to have been as absurdly unnecessary a structure as could be conceived.

"Enclosed between four walls forming a short wide oblong, it had a roof sloping all ways, crowned by a belfry such as one sees over the stables of a country house. The pulpit occupied the middle of the south side, the pews facing it from the north, the east, and the west, and a gallery occupying the north side, in the centre of which were perched the singers and the band of clarionets, bass-voles, &c., by which their performances were accompanied. The font, I well recollect, was a washhand-stand with a white basin!"

The ministry of Sir Gilbert's father appears to have been of an Evangelical type, and although unmarked by anything like cant or pretence, a breach always seems to have existed between him and his clerical neighbours of the "high and dry" type. Not that their orthodoxy had anything in

* Personal and Professional Recollections of the late Sir George Gilbert Scott, R.A. Edited by his son, G. GILBERT SCOTT, F.S.A. London: Sampson Low, Marston, Searle, and Rivington.

common with modern High Church views; they hated enthusiasts and Methodists, especially the latter; one jovial old parson in particular, when led the worse for his cups through the quadrangle of his college, piously exclaimed, "All this I do to purge my college from the stain of Methodism!" Practically, says Sir Gilbert Scott, these men were Pelagians, "hating the Evangelicals, not so much on account of difference of doctrine, but because the latter pressed religion and piety as the chief end of their teaching, while the 'high-and-dry' men did not care or take the trouble to do so, the fact being that they were not religious men." The isolation of the Scott family, consequent on the churlish neglect of their neighbours, was so complete that but for the gentle manners of his parents—especially his mother—and for contact with the pupils taken by his father, Sir Gilbert says, "I cannot conceive to what degree of rusticity we should have fallen." Some of the Gawcott rustics, indeed, seem to have been of a queer race, and the reader will probably chuckle over the humorous sketches of "Mother Warr," "Nanny White," "Cracky Meads," and "Tailor King." Like that of many other country clergymen of limited means, the Scott family was "a large and rapidly increasing one," and the reverend gentleman, having spent all the attention and energy he could spare from his pupils on his two elder sons, Sir Gilbert came off badly. Too poor to send him to school and too busy to teach them himself, his father let him "slip through between wind and water," his one great relief from this life of heedlessness and rough handling being the visit of the drawing-master, a Mr. Jones, of Buckingham, who had studied at the Royal Academy and attracted the favourable notice of Sir Joshua Reynolds, but foolishly returned home to his native village to support himself as a drawing-master and portrait-painter, instead of following up his profession in London. Visits to Stowe, the seat of the Duke of Buckingham, and to Hillesden seem to have awakened a regard for architecture in Sir Gilbert Scott's mind. Stowe was a very fine place, the house having a frontage of 1,000ft., and its owner, the grandfather of the present duke, was afflicted with the traditional land-hunger of the English noble. "He literally," says Sir Gilbert Scott, "came under the woe pronounced upon those 'that lay field to field till there be no place, that they may be placed alone in the earth,' for he nearly ruined the family by purchasing estates with borrowed money, the interest on which exceeded the rental." Hillesden Church was the building which first directed Sir Gilbert Scott's attention to Gothic work. This building, which he restored in later life, was begun in 1493 by the monks of Nulley, and is a very exquisite specimen of this latest phase of Gothic architecture.

"In plan it consists of a nave with aisles and quasi-transsepts, a large chancel with north aisle, a sacristy of two stories at the north-east angle of the chancel aisle, the upper story of which is approached by a very large newel stair at the extreme north-eastern angle. This stair-turret is a very exquisite and striking feature, being finished with a sort of crown of flying buttresses and pinnacles, of which I have seen no other instance, indeed it is one of the most beautifully-designed features I know.* The upper sacristy has a series of radiating loop-holes looking into the church. The walls of the chancel are ornamented by stone panelling. The ceilings throughout had panels of plaster, with wood mouldings. I have since seen some which had unhappily been taken down, and found the plaster to be in thick and very hard slabs, on which were set out curious geometric figures, drawn with the compasses, as if to form the guides for painted decorations. The rood-screen was perfect, and of exquisite beauty. The fittings were nearly all of the original date, and very good,

though, of course, of very late character. The chief exception was the great square pew of the Dentons, a somewhat dignified work of Charles the Second's reign, furnished with great high-backed chairs."

Sir Gilbert Scott's father was so much interested in the church that he urged the Duke of Buckingham to repair it, "the result being that his Grace whitewashed the exterior of the tower!" The churches of Maids Morten, Tingewick, and Chetwood also attracted the attention of the future architect. Of the latter, he says—

"I was never more astonished than when I first saw this church, never having before seen or heard of 'Early English' architecture. It is a fragment of a small monastic church, and its east window consists of five noble lancets, with, externally, plain but bold detail. On either side are fine triplets. Never having before seen such windows, I was greatly perplexed at them, and, failing to get the key, and being reduced to peeping through the keyhole of the west door, I was astonished and puzzled to find that the east windows had shafts with foliated capitals, a thing I had never seen and could not understand. I remember continuing all day in a state of morbid excitement on the subject, and having no access to architectural books, it was very long ere I solved the mystery."

The boy's evident predilection for old churches first led his father to think of making him an architect, and a consultation with his uncle King led to an offer from the latter to take his nephew under his charge and give him some instruction in architecture, of which Mr. King possessed a very fair knowledge. He initiated the young student into Classic architecture. One friend lent a copy of Sir William Chambers' work, another, a portion of Stuart's Athens, and so, says Sir Gilbert, "I was able to follow up architectural drawing, as then taught, pretty systematically, and by the time I was articled I had been already put through my facings to a certain reasonable extent." He thinks he "also had access to Rickman"; anyhow he got to know the ordinary facts as to the different periods of Mediæval architecture. He stayed with his uncle, on and off, about a twelvemonth, during which time his relatives were on the look-out for an architect to whom to article him, and regarding whom "it was a *sine quâ non* that he should be a religious man, and that his terms should be moderate." The profession must have been in a dreadful condition in those days, worse even than now, for Mr. Charles Dudley, a travelling agent to the Bible Society, told Scott's relatives "that there was scarcely a religious architect in London." He at last recommended Mr. Edmeston, better known as a poet than as an architect, and to Mr. Edmeston, accordingly, Gilbert Scott went, at Lady-day, 1827—just about the time his father had managed to collect funds for the rebuilding of his own church, of which job he was his own architect, and regarding which his son remarks, he "cannot say much about design or execution; but these were days to be winked at, as no one knew anything whatever about the subject."

The first remark of Mr. Edmeston, with whom Gilbert Scott now took up his abode at Homerton (his office was at Salvador House, in Bishopsgate-street), was not favourably calculated to induce any strong predilection for Gothic work. Mr. Edmeston declared the cost was so great as to be almost prohibitory. He had once tried it at a Dissenting chapel he had built at Leytonstone, and the very cementing of the exterior amounted to a sum which he named with evident dismay! Few will learn with surprise that his new pupil was disappointed in his master. Sir Gilbert Scott says:—

"I had no idea beforehand of the line of practice followed by my future initiator into the mysteries of my profession; I went to him with a mythic veneration for his supposed skill and for his imaginary works, though without an idea of what they might be. The morning after I was deposited at his house, he invited me to walk out and see some

of his works—when—oh, horrors! the bubble burst, and the fond dream of my youthful imagination was realised in the form of a few second-rate brick houses, with cemented porticoes of two ungainly columns each! I shall never forget the sudden letting down of my aspirations. A somewhat romantic youth, assigned to follow the noble art of architecture for the love he had formed for it from the ancient churches of his neighbourhood, condemned to indulge his taste by building houses at Hackney in the debased style of 1827! I am not sure, however, that I was any very serious loser from this. Mr. Edmeston's practice was a mere blank-sheet as to matters of taste, and left me quite open to indulge in private my old preferences, or to choose in future what course I pleased."

He acknowledges, too, that he learned much in the office of the common routine of building, specifying, &c. which he might have missed in a better one; he found a kind home with Mr. and Mrs. Edmeston, and the years of his pupilage seem to have passed pleasantly enough. During the last of the four through which his articles extended, he took lessons of Mr. Maddox, an architectural drawing-master of great talent, whose tuition appears to have been more congenial than his tenets, for "he was an infidel, and his conversation on such subjects was truly appalling." Among his fellow-pupils here were Edwin Nash, Morton Peto, who had just left Decimus Burton, and Thomas Henry Wyatt. An attack of small-pox, and the grief resulting from the death of his favourite brother Nathaniel, who had also come to London, and who was taken away by brain fever at the early age of sixteen, are related as the only disturbing incidents of this period of Sir Gilbert Scott's life. Towards the end of his articles, Moffatt, who subsequently became his partner, came into his office, and his readiness to acquire knowledge, coupled with his practical familiarity with building construction, won for him the admiration of Scott, upon whom, to a considerable extent, the duty devolved of imparting to him the rudiments of architecture.

The termination of Scott's articles, about Lady-day, 1831, was followed by a month's visit to his uncle King, at Latimers, where he fell in love with his cousin, Carry Oldrid, who afterwards became his wife. A couple of months at home, and a visit to his eldest brother at Goring, were succeeded by a journey to Hull, during which he paid flying visits to Lincoln, Peterborough, York, Selby, and other places of interest. Returning to London, and acting on the advice of Mr. Waller, a well-known surveyor, he placed himself with Messrs. Peto and Grissell, giving such services as he could render, and having in return the run of their workshops and of their London works. The advantages derived during his stay here Sir Gilbert declares to have been considerable, but it did not last long, for it was necessary he should do something for his living, and Mr. Peto did not quite relish his young assistant's prying so closely as he was wont into the foundations of the prices of work and materials. Scott accordingly, some time in 1832, entered the office of Mr. Henry Roberts, who had then recently obtained by competition the appointment of architect to the new Fishmongers' Hall. He was the only clerk in the office at the time, and had the advantage of making all the working drawings for that building, from the foundation to the finish. The engagement lasted two years, during which time Scott got his first drawing hung in the Academy, and ventured into one competition—for a grammar school at Birmingham. The superintendence as clerk of works of a small work at Camberwell concluded his engagement with Mr. Roberts—"a dull, blank period," during which "Smirkism and practical work chilled his own tastes," and he then determined to get into practice on his own account, previously taking three months' holiday, part of the time being spent with his parents at Wappenham, in Northampton-

* Its design was reproduced by Sir Gilbert Scott in the angle turret of the new buildings at King's College, Cambridge.

shire, to which living his father had been preferred by Bishop Kaye, and where he had built a new parsonage-house from a very "ugly design" furnished by his son. About Christmas, 1834, on the advice of his friend Kempthorne, who had been recently engaged by the Chief Commissioner of Works to prepare normal designs for the proposed new unions to be erected under the Poor Law Act, which had then just come into operation, Scott took a set of chambers next to those of the former in Carlton Chambers, Regent-street, and was soon busy helping his friend "on work even more mean than that of my pupilage." This, however, did not last long, for the heavy tidings of his father's sudden death rendered it imperatively necessary for him to take steps to secure his livelihood, since he could look for no more assistance from home. His first course was to send circulars to every friend he could think of begging their patronage; his next to quit Kempthorne, and obtain the appointment of architect to four unions in the district where his father had been known. In a few months, by dint of hard work, he found himself in what was to him a good practice, though for a time unproductive, and involving considerable outlay, in which he was helped by his mother, and by the receipt of his share of a fund which was subscribed as a testimonial and a help to the descendants of the commentator, his grandfather. The next few succeeding years are described as an "era of turmoil, of violent activity and exertion." For weeks he almost lived on horseback, canvassing newly-formed unions. Long coach-journeys and meetings with guardians alternated with periods of close work in his little office at Carlton Chambers, and brief periods of relaxation mainly spent with his mother at Wappenham, where his brother had succeeded his father as rector. Moffatt, who had accepted his invitation to help him with his working drawings, and had been recommended by him to superintend a little circuit of buildings within a few miles of one another, attracted the notice of a Wiltshire magistrate, who used his influence to obtain for him the appointment of architect to the Amesbury Union Workhouse. Moffatt took the appointment, and the drawings were made in Scott's office. Thus was brought about a somewhat anomalous state of things. Scott was architect to four union workhouses in one district, to which Moffatt was clerk of the works; while Moffatt was architect to one in a distant part of the country, the drawings for which were made in Scott's office. This led Moffatt to make a proposal which Scott accepted, and which became the foundation of their subsequent partnership. The effect of the arrangement is described by Sir Gilbert as "magical." Moffatt followed up union-hunting into Devonshire and Cornwall with almost uniform success; and Scott's own poor little quartette of works round his old home soon became as nothing compared with the engagements which flowed in upon the partners.

In 1838 Sir Gilbert married his cousin Caroline Oldrid, and about the end of the year settled down at No. 20 (now 31) Spring-gardens, where their first and second sons were born in 1839 and 1841. From this date Scott's practice began to take a more legitimate and less abnormal line, the pursuit of which we must postpone till next week.

(To be continued.)

BILLS OF QUANTITIES: THEIR PROPER RELATION TO CONTRACTS.*

(Concluded from p. 618.)

THE remaining system to be considered, that practised in Glasgow, shares its favours more equally. By it the proprietor is entirely relieved

from responsibility connected with the quantities; he is called upon to pay only for what he gets, and the contractor gets paid for what he does and nothing more—nothing being referred to in the final measurement except what has been actually done and measured.

This mode of contracting is by no means free from drawbacks, but it is the logical consequence of the interference of the proprietor or his architect with the preparation of the schedule of quantities, and I can see no escape from it. It has many excellent points: for example, it solves the difficult question of responsibility which we have just been considering, and supplies the only substitute for a guarantee of absolute accuracy which has been practically tested. The experience of many years has proved that this substitute is complete and satisfactory, or as nearly so as the circumstances permit. The arrangement is equitable, and it deals impartially with the two parties chiefly interested, which, as we have seen, the other systems do not. Even clerical errors are as likely to benefit the one as the other, and there is always the check of the second measurement *de novo*. The result is, that all cause of quarrel and excuse for complaint is removed, actions connected with contracts are almost unknown, and the system altogether works satisfactorily on this solid and intelligible basis: the mutual convenience and interests of the parties. The defects of the system have recently been the subject of discussion before the Glasgow Architectural Society. They are almost entirely of a kind which would vanish before a little determination and co-operation on the part of architects and measurers; and I have no doubt that some improvements will very soon be introduced. Passing from this, I must notice one objection which is often urged against the system, namely, that it leaves a proprietor in uncertainty as to the cost of a building till it is finished and measured. But this is not so, unless the architect has neglected his duty in the preparation of proper plans and specifications. But if an architect neglects his duty in this respect, the proprietor is not relieved from this uncertainty by any other system, as it is then impossible to foresee the probable extras. If it were otherwise the objection would be fatal to the Glasgow system; but if the experience of a hundred years proves that there is no likelihood of any discrepancy between the estimate and the measurement—that practically there is none, except where it can be clearly traced to the carelessness of the architect or the measurer—then it will be seen that there is little weight in the objection; because if the architect and measurer do their duty there need and there will be no difference between the measurement and the estimate; and if they neglect their duty it is perfectly obvious that, in justice both to the proprietor and the contractor, there ought to be a difference, and the two offenders, or either of them, should at least suffer in their professional reputation.

It can, I think, be proved that with equally explicit plans and specifications there is less chance of the final account exceeding the tender under the system of remeasurement than under any other; and not only so, but (and this is an important set-off against some uncertainty) the work is done at lower rates than if it were not to be remeasured. It is only in localities such as Edinburgh and Glasgow, where contractors are accustomed to both systems, that a comparison in this particular is possible, and there it has been abundantly proved. I have been assured by contractors of high standing and long experience that they invariably charged from 10 to 15 per cent. more for work which was not to be remeasured, besides a considerable sum to cover contingencies; so that, when the work is remeasured, not only does the proprietor pay only for what he gets, but he pays from 10 to 15 per cent. less for it; and this, you will admit, is a very substantial advantage. Another objection which may be fairly urged against the Glasgow system is that it has a tendency to encourage carelessness in the preparation of the documents necessary for obtaining an accurate estimate. Knowing that all will be made right at last, the architect is tempted to pass the plans on to the measurer in an incomplete state, and the measurer to assume quantities which, in consequence of that incompleteness, cannot be exactly ascertained. The undue haste of the architect, it is true, is often the result of undue pressure from the proprietor, who does not realise how necessary ample time is for the preparation of complete working drawings. By resisting this urgency

we may escape the danger on the one side, and by exercising proper authority over the measurer we may escape it on the other. Of defects of a more accidental character I shall mention only two. One is, that the facilities afforded by the system for obtaining estimates encourage young men to undertake work on their own account before they are properly qualified to do so. A man who could not write a specification himself gets an experienced measurer to prepare schedules for him, who thus gives him the benefit of the specifications of others. Another defect is the undue delay which usually occurs in settling accounts. This is caused chiefly by measurers neglecting old work for the sake of securing new: to such an extent is this sometimes carried that I have known premises entirely and satisfactorily finished and occupied for twelve or eighteen months before the tradesman's balances could be ascertained. This, I need hardly say, leads to much inconvenience, and frequently to heavy and undeserved loss, both to contractors and architects. I endeavour to mitigate this abuse by employing several measurers, instead of confining myself to one or two, which would really be much more convenient and agreeable in many respects. But there is no reason why the evil should exist at all; and it might, with other abuses, be entirely swept away, if architects would co-operate and take a more complete control over all the operations of the measurer.

It may, perhaps, occur to some to suggest another objection to the system—namely, that it is impracticable—that it is, in short, impossible to remeasure a large building; but that objection is very easily disposed of. It is not only practicable, but it is constantly done, and buildings of every size and complexity of detail have been measured when finished in Glasgow and neighbourhood during many generations; that question, therefore, need not be discussed. I must now hasten on to consider the last division of my subject.

III. *Proposed Changes.*—What I have already advanced points to these conclusions: First, that the usual practice in contracting is radically defective, being based upon false principles, which are inimical to the essential requirements of any tolerable system—namely, that it should insure justice to both parties to the contract; and, second, that the practice of making the schedule the basis of the contract and remeasuring the work when finished is sound theoretically, and practically efficient. If this be so, it necessarily follows that it is the duty of our profession to make considerable changes in the direction of adopting the good features of the remeasurement system, eliminating the bad, and guarding against its accidental abuses. This involves an entire change in the relation of the bill of quantities to the contract. In short, if we take any cognisance of the quantities at all, we must, in justice to our clients, recognise them to be, along with and quite as much as the plans and specifications, the basis of the contract. I have not said that that course is preferable to our taking no cognisance of quantities at all; but what I do insist upon is, that we must adopt either one alternative or the other—either to have *nothing* to do with quantities, or to have *everything* to do with them; either to allow the quantity-surveyor to be entirely the servant of the contractor, or entirely the servant of the proprietor, and therefore our servant, directly under our guidance and control.

I have thought it advisable to occupy the time at my disposal to-night chiefly in exposing the errors of existing systems, feeling that it was impossible on this occasion both to treat that part of my subject with sufficient detail and also to explain various modifications of the remeasurement system which might be advantageously introduced. Besides, I am sensible that it is vain to talk of the details of reform if I fail to convince you that reform is needed. I cannot indeed believe that the members of the profession generally are content with matters as they stand. Recent discussions of kindred societies; recent articles and correspondence in professional journals; and recent opinions of counsel and actions before our courts of law, all indicate at once the existence of widespread dissatisfaction and its justification. Indeed the time seems rapidly approaching, if it has not already arrived, when we shall be compelled to deal with the whole subject in a liberal and resolute spirit. Meantime, I shall only further trespass on your patience in the hope of extending the scope of the discussion by making, in conclusion, one or two

* A paper read by JOHN HONEYMAN, F.R.I.B.A., Glasgow, before the Royal Institute of British Architects, May 19th, 1879.

additional remarks on the remeasurement system, towards which we seem gradually approaching. An ideal contract would secure for the contractor payment for everything he was required to do at certain prearranged definite rates, or, where these do not apply, at current rates; and, on the other hand, it would secure for the proprietor full and just value for every penny which he was required to pay. Now this ideal is very fairly realised if the work is carefully measured and priced to begin with, and again carefully measured and priced when finished. The whole thing is remarkably simple; there is no mystery or difficulty about it. For the sake of illustration, I submit copies of the estimate and the final measurement of a piece of work which has been actually completed. For convenience, I have selected a very small estimate; but the largest are framed exactly in the same way, and are quite as easily understood. It will be observed that, after deducting half of the measurer's fee, the final account comes to 7s. 7½d. less than the estimate, although it includes two additional chimney cans at 6s. 6d. each, and an extra quantity of felt costing 15s. 2d. For both of these extras the contractor gets paid at the rates contained in his estimate, and he is perfectly satisfied. No question about what ought to be charged can be raised, and if any doubt should arise as to whether the extra cans are on the building or not, that being a matter of fact and not of opinion is very easily settled. All parties have good grounds for satisfaction with such an arrangement; and I may add that there is no difficulty in dealing with every variety of work in the same way. It may be interesting as indicating how successfully such a system disposes of all legal difficulties, and how well it works even with its present defects, if I mention that on taking a hurried retrospect of my own experience since I commenced business on my own account, I find that I have accepted upwards of 1,100 tenders for the principal departments of work connected with buildings, besides innumerable offers for specialities; I have had to cancel contracts, to supersede bad contractors, to get rid of bad contractors and arrange with their creditors without allowing the interests of my clients to suffer, to make deductions from contractors' claims; and, generally, to do all the varieties of disagreeable work usually devolving upon us in connection with such matters; but the lawyers have had nothing whatever to do with these 1,100 contracts, and not one single action at law has emerged in connection with them. A system capable of producing such results would doubtless, if freed from its admitted defects, prove generally acceptable and highly beneficial. In this matter, however, we are helpless, unless we act in unison, and we naturally turn to such a body as this Institute for guidance.

It will be observed that the proposed changes which I recommend are: a radical change in the relation of the bills of quantities to the contract, and subordinate changes which will then be expedient. I shall now only venture to mention one of these. Assuming that the system of remeasuring is generally adopted, it will be found that in some respects the interests of architects will be more directly affected than at present by the conduct of the measurers, and it has occurred to me that many of the minor defects which we find in the working of the system might be removed and the interests of the profession protected, if measurers were not allowed to practise—in other words, if they were not employed by architects—unless they held a certificate of competency from the Institute. This at first sight seems rather a startling proposal; but after a good deal of consideration I believe it to be practicable, and I am certain that, if carried out, it would be beneficial. I may not now expound the many reasons which support this belief, but I may remark generally that, if a change in the mode of estimating is introduced, such as I believe to be necessary to meet fairly the exigencies of the case, it is evident that it will rest entirely with the architects of the country to determine the exact position which the measurers shall hold, and the functions which he shall perform. In the altered circumstances, indeed, architects might with perfect propriety measure their own works, or even make measuring a branch of their business; although I may say that, personally, I regard such a course with strong repugnance. Now, in suggesting such a comprehensive stretch of the Institute's authority, it must not be supposed that I speak merely as a member of the Insti-

tute with an exaggerated idea of its cosmopolitan influence. I know very well how far short it comes of our ideal; but it is nevertheless all we have in the shape of a national professional association, and in such matters of general interest it is bound to assert itself, and to direct and govern the current of reform. Were I not a member, I would be equally solicitous that the Institute should take the matter in hand; and this feeling will, I am sure, be shared by members of the profession throughout the country. It is to be regretted that every one who is duly qualified is not a member. It is needless to point out how immensely such union would strengthen our position as a profession when we come to deal practically with measures such as these, directly affecting us all. I am confident, however, that in introducing changes in our mode of contracting, which may generally be acknowledged to be beneficial, the Institute might safely calculate upon the active and hearty co-operation of all members of the profession throughout the country. Even now the representative character of the Institute, and its value as the only organisation which can efficiently deal with professional difficulties, is more generally recognised than it has ever been before; and I am sanguine enough to believe that that recognition is destined to be progressively more cordial, more universal, and therefore more energetic.

THE FURNISHING OF TOWN HOUSES.

A SUGGESTIVE paper on this subject was read before the Society for the Fine Arts on Thursday evening by Mr. R. W. Edis, F.S.A., in the west gallery of the Architectural Union Company's premises; ladies formed a large proportion of the audience.

That the articles with which we are daily to be surrounded in our homes should be selected for utility and not for show; that ministration to personal comfort and convenience is a quality second only to solid construction and sound workmanship in furniture intended to be constantly used; that it is preferable that our household goods should be made of common, even base materials, well put together, and tastefully decorated, than that we should expend an equal sum of money on others, in which greater intrinsic worth in the substance worked is made a set off against flimsy fashioning and insufficient quantities; that everything in a house should be "fitted for a place, and subordinate for a purpose"; these general rules have, as Mr. Edis apologetically admitted, been deserted upon to triteness. Whatever freshness or interest characterised the lecture lay partly in the way in which these commonplace of furnishing were treated, but more in the detailed modes in which the author proposed to apply these principles to the requirements of these furnishing town houses. The manner in which furniture has followed each change of style, from Greek to Roman, from Gothic to Queen Anne, without being thereby any more closely adapted to the everyday wants, was traced with some tautology and repetition, it being suggested that the only gain in these alterations of fashion is a change of special inappropriateness and particular feature of discomfort. Stress was laid on the point that, if furniture be chosen because it is now in the height of fashion, should it be durable, it will, of necessity, presently look out of date, the obvious moral being deduced that only articles of permanent interest should be purchased, to the avoidance of mere fashionable conceits and passing eccentricities. The higher cultivation of the individual, and as a sequence of the whole community, in the art of furnishing, is not, it was remarked, to be arrived at by setting up any particular style of design, or blindly accepting the dogmas set up by interested persons, but by the inculcation of broader views of the uses and purposes of our furniture, and a consideration of the ways in which the several articles that can be so selected as to form a convenient and harmonious whole. The mode in which the ordinary artwork manufacturer endeavours to foist upon the public his vulgarities, at once clumsy, commonplace, ill-conceived, and costly, under the names of "Old English," "Queen Anne," and "Chippendale" was exposed, but at the same time the author fully recognised the important progress made by some of our leading firms, such as Gillow and Co., Morris and Co., and Collinson and Lock, who have practically spared no pains to produce

the best possible work, and have associated with themselves in the endeavour to provide furniture of good design and workmanship a number of artists of high repute and knowledge. In much of the work of such firms as these, there is evident a regard for harmony of design, as well as for use and suitability, attributable, he thought, in great part to the fact that the designers are not mere preparers of drawings and patterns for chairs, tables, and curtain hangings, but men who, like the artists of the middle ages, believe that every creation of design should be honestly and carefully thought out, whether in the smallest fitting of a house, the commonest colouring of a wall, or the decoration of the smallest panel in a buffet or cabinet, as the most gorgeous edifice, the most exquisite painting, or the most noble piece of sculpture. As an architect he regretted that in these days the designing of furniture has so largely passed into the hands of the upholsterer; and it will be well for art if artists of every class shall think it not derogatory to their rank to conceive and design the lowliest piece of furniture, or the pattern and colouring of wall hangings and floor coverings. A room may be furnished simply and well, usefully, comfortably, and artistically, without of necessity making any enormous outlay. Why should not deal, and other soft woods, he asked, be employed more largely for the construction of such furniture as buffets and panelling, wardrobes and ottomans? Mr. William Burges has shown how artistic ideas can be worked out with the greatest elaboration of colour and ornamental design, and figure decoration, on quite plain surfaces of the softer woods, and the author knew no reason why deal, painted and varnished, should not be largely availed of for much of the internal and subordinate woodwork of our houses. Under the general title of furniture, which properly represented anything movable, he proposed to include all the general fittings which are usually nowadays called fixtures, such as hanging-closets in bedrooms, shelving, built-up buffets, and such ordinary carpenters' work, which, he suggested, may well and economically take the place of the more expensive pieces of furniture, and, he added, that these shelf-clusters or closets need not of necessity become the property of a landlord at the end of a lease; they can all be made separate and distinct, to fit in their various places, and be screwed into blocks or hanging pieces fixed to the walls. For recesses such fittings can be made much more inexpensively than the usual movable furniture, and can be adapted to the general planning of the room. Mr. Edis seemed to have a housemaid's hatred of dust and dirt accumulators, and offered many hints as to modes of obviating the occurrence of dark corners and inaccessible spaces and crevices. On this account all intricate machine carvings, and unnecessary ledges and frettings, were condemned as bad, and traps for filth. Sideboards, buffets, wardrobes, and similar articles of furniture, should either be brought to the floor with a bold plinth or supported on plain, well-turned legs of sufficient height to allow a brush to be used beneath them, and care should be taken that no unnoticed dust-holding receptacles exist on wardrobe-tops just below the ceiling-level. Instead of so accurately fitting the carpet to the contour of the room that it becomes difficult to take it up for cleansing purposes, he suggested that the borders of all floors should be painted, and a few small Persian or Indian carpets laid where most needed for comfort. The machine-made mantelpieces most usually seen in London houses were condemned as commonplace in character, abominable in design, and bad in form, outline, and construction. To leave these as they are would utterly destroy all decorative effect in the room, and he would say, take them down carefully and remove the grates and stoves all away in some cellar, from whence they can be brought to light and refixed when your lease is up. Any new mantelpiece put up in its stead should be fixed as a piece of furniture, removable without damage to the walls. In the dining-room it may be of unpolished wainscot or American walnut, with a lining of black or golden Siena marble, the lower panels filled in with painted subject-tiles or delicate carving of fruit, the main shelf being broad enough to take a clock or other ornaments, with perhaps a centre panel for a portrait or subject picture, enframed in boldly carved moulding. On either side might be plain wainsot panelling carried up to the ceiling line,

or tiers of shelves for bric-à-brac or china, and the top finished with a carved cove, filled in with stamped leather or gilt enrichment. For the drawing-room and library the design of the mantelpiece would require some modification; in the former might be subdued delicate embroidery, painted tiles or Japanese lacquer panels, having recessed shelves, lined with velvet, to set off the vase, china, or glass, the sides formed into groups of shelves or brackets, and the centre filled with a splayed Venetian glass, not at so great a height from the ground as to be rendered useless, and of sufficient size to reflect the works of art in the room. In the library small flanking cupboard may be arranged, with shelves for china or books, so as to carry on the general furniture of the room. If the fireplace can be recessed, this may be lined with decoration tiles in panels, with angle brackets for larger pieces of china or other ornaments. Many persons, it was remarked, do not hesitate to spend from £20 to £100 upon a picture which, while beautiful in itself, cannot give half the delight, pleasure, or variety as half the same sum of money expended upon a really good mantelpiece. In small bed or dressing-rooms for bachelors it was suggested that the mantelpiece may form a sort of dressing-table, having above the shelf and on either side of a large looking-glass cupboards; the mirror could be flanked by light movable brackets for gas or candles; the whole of the woodwork could be of stained and polished deal. In like manner, the lecturer conducted his audience through a London house, "upstairs, and downstairs, and in my lady's chamber," suggesting at every turn some arrangement for providing additional comfort and refinement. In the narrow passage-way dignified in London by the title of the hall, Mr. Edis proposed to place one or two chairs of plain oak or a long deal settle, with plain rail back and elbows, and incorporated with the latter, a small umbrella-stand, having a zine tray at the bottom and a curved brass rail at the top; in the inner hall a simple cupboard, with sliding doors, and containing shelves for coats, and a sliding rack for hats, and hooks or pegs for sticks and umbrellas above; the top may be made of unpainted oak or marble for use as a serving table. On landings a divan or stuffed seat of the plainest description may be placed, and over it may be thrown a piece of coloured stuff or silk, receptacles for plants or flowers being arranged at each end. In the dining-room everything should be as comfortable and convenient as possible, designed for use, not show. The chairs should be broad-seated and backed, the seats and backs stuffed with strong serviceable leather or morocco; he hardly liked to hint at rush bottoms, but he believed these to be as comfortable as leather, and, if made in various colours, pleasant to look at. In addition to these, there ought to be two arm-chairs, of ample dimensions for comfort in carving, &c., and one or two lounge chairs. The most sociable table is a round one about 4ft. 8in. or 5ft. in diameter on one massive central support, expanding into an elongated oval. Nothing shows off flowers and silver better than an ebonised top left open in the centre with good linen slips on the sides for dinner, removed before the wine comes in. Instead of the ordinary sideboard a solid buffet would be preferable, the lower portion being fitted with a collaret and liqueur tray; within a panelled cupboard front on one side and a cupboard and drawers for plate on the other; for convenience in serving the central portion may be made with a sliding hatch communicating with the room behind, or there may be a light lift from the basement. The panels of the doors when sufficiently high to be seen may be filled in with low carving in relief in box or other hard wood, or with marquetry or Japanese lacquers. Panel painting is preferable for decorative purposes to carving, turning, or fret work. Good deal panelling painted of some warm colour, if free from elaborate mouldings, is almost as inexpensive as some of the gorgeous pattern flock papers painted in several tints with which it is considered necessary to make dull and heavy the walls of many a London dining-room. For lighting a central hanging lamp with good shade of subdued or warm-tinted glass is far preferable to any contrivance for burning the filthy compound which the gas companies are content to give to us long-suffering inhabitants. For hangings, there are innumerable varieties of tissues from which to select, and on the walls of the room were hung a number of specimens of coloured damasks, lent by Mr. William Morris. A plain brass rod, or

piece of 1½ in. gas-piping, painted, is ample for curtain-rods. Nothing, the lecturer thought, can be worse than the heavy, lacquered brass or wood poles and unmeaning friezes or valances, which only serve to hide dust, and are execrable in taste. The library should be as comfortable as possible, with broad easy-chairs, low centre-table, with plenty of drawers and pigeon-holes, and a large pedestal-desk, with circular revolving top, to shut up on papers; everything should be arranged for preventing the accumulation of dust, and for this reason the floor ought to be painted all over. The room should be surrounded with bookcases, with sliding-fronted cupboards for periodicals, and drawers for prints and photographs, and all the shelves can be made of plain deal, stained and polished, and fitted at the cornice-level with spring-roller blinds, which can be drawn down at night and fastened with a clip, so as to preserve and protect the books. No set rules can be given for the furnishing of the drawing-room, as that must largely depend on the good taste of the lady of the house. Any, and every, class of decoration and ornament may here be brought together, so long as there is some sort of careless harmony of grouping and colouring. We do not want, he said, our drawing-rooms to be filled with stiff, uncomfortable furniture; nor yet to be museums in which we fear to walk or move about; nor yet showrooms from which the coverings are removed only on grand occasions; but we require pleasant, cheerful rooms in which the collection of furniture and objects of art shall tend to make them more homelike and habitable. By all means have works of all kinds of art surrounding you; but, depend upon it, your enjoyment of them will be materially increased if they are carefully arranged and harmoniously set out. Attention was drawn to a small circular satinwood cabinet of the Adams style, lent for the evening by Messrs. Gillow and Co., which last year was exhibited in the boudoir of the Princess of Wales's pavilion at the Paris Exhibition. The lecturer said he regarded it as one of the most delicate and graceful pieces of modern furniture which he had seen. The panels are of walnut wood, with ebony inlaid, and laid over with box-wood, carved down so as to show the ebony within in exquisite cameo-like medallions after Flaxman; the enrichments and the ornamentations are of gilt lacquer-like character, exquisite in design and beautiful in workmanship. Such articles as these are well suited for the drawing-room, in which everything should be bright and artistic, with general grace and quietness of design, and colouring throughout. As the bedrooms of a London house are, as a rule, sacrificed in height to the reception rooms below, it is desirable to utilise every corner and recess without filling the rooms with heavy and inconvenient furniture. The recesses formed by the fireplaces should, in part at least, be filled with hanging closets, which can be screwed to the walls and removed at will, carried quite up to the ceiling; the whole may be fitted with shelves, hooks and rails, and sliding shelves, and drawers, and enclosed with folding-doors in two heights, the lower panels being filled with plate glass. In the dressing-table might be nests of drawers on either side of a cupboard in the lower portion. If any panels in the room are decorated at all, let it be done with some pleasant drawing in monochrome or diaper enrichment; which shall not suggest spottiness and crudeness to those who have to lie long hours and look at them. He could not agree with the fashion which is endeavouring to revive the heavy wood bedsteads of our ancestors; nothing can be better or more cleanly than painted iron or brass bedsteads with light hangings, cheerful yet subdued in colour. A variety of patterns of printed cottons and cotton tapestries, lent by Messrs. Morris and Co., were exhibited, and should these be too sombre in tone, the lecturer suggested that Indian printed cottons, commonly called "sambars," should be procured, or some of the Indian silks with cotton backs, which can be bought for something less than 2s. a yard; specimens of these, lent by Mr. Graham, were referred to. One suggestion made by Mr. Edis, which would appear to need a good deal of consideration on sanitary grounds prior to application in any instance, was that if it be possible to get waste-pipes away so as to empty free into the open air, and not attached in any way to the drains, instead of the ordinary washhand-stand with fittings of porcelain or earthenware so liable to breaks and damage, one

of the common tip-up basins should be introduced, fitted in a suitable frame, and with water laid on from the nearest cistern. This Mr. Edis regarded as infinitely more convenient and serviceable in all ways, and it would certainly, as he pointed out, save the domestic drudge a considerable amount of labour. In conclusion, the lecturer insisted on the point that the aim of all true art in furniture, as in everything else, should be to produce good work for the million, so that at a moderate cost things beautiful in design, detail, and colour may be brought into everyday use.

DOCK GATES.

AT the last meeting of the session of the Institution of Civil Engineers, held on the 27th of May, a paper was read on "Dock Gates," by Mr. A. F. Blandy, M. Inst. C.E.

The author commenced by defining the general features of a pair of gates and their surroundings, then passed on to the strains to which a gate was subject, and gave a formula for the pressure per unit of length. Examining the mutual action of the gates on each other, he stated that in practice this was liable to vary, and that three cases must be considered:—First, the gates might be constructed so that when under pressure the meeting faces of the mitre-posts bore fair and true against each other, and distributed the mutual reactions uniformly throughout the width of the meeting faces. Secondly, foreign substances, such as chips of wood, might intrude, or the gates might wear and become a little too short, causing them to nip on the dock, or inner edges of the meeting faces. Thirdly, the gates might be a little too long, in which case they would nip on the outer edges of the meeting faces.

The magnitude and direction of the primary forces acting on the pair of gates were next investigated, and it was shown that a point could be found on the centre line of entrance, the distance of which from any point on the back of the gate was proportional in magnitude to the resultant of all the forces acting on a section taken through the gate at the point measured to. It was also shown that, in practice, the line of position of these resultant forces in most cases corresponded with the arc of a circle drawn through the centre of the heel-posts and of the meeting faces of the mitre-posts. The effect of nipping would be to transfer this arc from the centre to the edge of the meeting face at which nipping occurred, and consequently to proportionately increase or diminish the bending moments on the gate.

The effect of direct compressive stress combined with bending moment when applied to various forms of structure, such as were common in dock gates, was then examined, and methods of finding the intensities and distribution of stress at a cross section by means of diagrams were described for three different forms of wooden gates, viz.: 1st. When the gate was formed of rectangular wooden beams. 2nd. When it was built in divisions corresponding to the voussoirs of an arch, and depended entirely on the arch-form for its stability; and 3rd. When the gate was built in divisions as in the second form, but of less curvature, and required the assistance of the supplementary connecting pieces, which must be taken into account when computing the strength.

Looking at the general features of the last-mentioned gate, the first impression was to regard it as a form of bowstring girder, but further consideration would show that this could not be, as there was nothing to transmit the longitudinal stresses from the "bow" to the "string," the transverse bolts being obviously insufficient for that purpose. When, however, the action of a bending moment caused the gate to deflect, the transverse bolts, though allowing the voussoirs and connecting pieces to slide on each other longitudinally, would maintain them laterally in their relative positions; consequently they would bend through similar angles, and the total moment of resistance would be the sum of the amount of resistance due to the voussoir plus the moment of resistance due to the connecting pieces.

In the case of trussed beams, the effect of direct compressive stress combined with the bending moment had to be considered, when applied to a rectangular wooden beam supplemented by wrought-iron truss rods. To illustrate this the simplest form of truss might be taken, namely, that consisting of a rectangular wooden beam supplemented by two wrought-iron truss rods

and a king-post, and it might be assumed that the king-post was inelastic and of infinite strength. It would occur to the observer, that the stresses on the different parts of such a system might vary indefinitely, according to the method of attaching the rods to the beam and also to the extent of initial stress put upon the rods before the system was subjected to extraneous pressure. Certain conditions must therefore be assumed before an investigation of the stresses on the different parts could be attempted. If strength only was considered, the best adjustment appeared to be that which, when the system was under pressure, caused the whole bending moment to be borne by the truss rods, and left the timber over the king-posts entirely free from transverse strain.

Formulae for the stresses on the various parts were then given, and it was demonstrated that if the truss were cambered or allowed to sag, then the stresses would be increased, and the best condition of adjustment was the one first assumed. To attain this condition, if the beam was continuous from end to end, the system when under pressure must have a certain deflection, viz., one-fifth of that which the beam would have if there was no system of trussing. The condition of the system when the pressure was removed was next examined, and formulae were given for ascertaining the camber which it would assume. The intensities of stress on the various parts were also investigated, formulae for the same being given, together with methods of showing those intensities by diagrams. A similar analysis was also made supposing that no working deflection was allowed.

In the case of wrought-iron gates, the point to be considered was the effect of direct compressive stress combined with bending moment on a wrought-iron girder composed of flanges connected by a centre web. The position of the neutral axis was investigated, and methods by diagrams were described; first, for finding the intensities and distribution of stress on any given section; and secondly, for designing a section of such proportions that the intensity of stress on any fibre should not exceed certain limiting intensities of tension and compression. When the method of finding the principal stresses, as explained, was considered in connection with the effect of a bending moment, there could be no doubt but that, theoretically at least, the most advantageous form was that on which the water-pressure produced no bending moment, that was to say when the line of the centres of gravity of the cross sections corresponded with the centre line of the gate, and when the centre line of both gates formed together one continuous arc of a circle extending from centre to centre of the heel-posts, and passing through the centre of the meeting faces of the mitre-posts. The author showed that when this form was departed from the increase of metal would be as rapid as the gate was flattened, nor would any appreciable reduction in the cost per ton occur, until the gate was reduced to the absolutely straight form, when the increase of metal would, in the author's opinion, more than counterbalance the decrease in price supposed to arise from the use of unbent plates.

As regarded the rise, Mr. Bramwell had pointed out that the most economical form of gate was that in which a pair of gates when shut formed a continuous arc subtending an angle of $133^{\circ} 56'$, at the centre of the circle of which the said arc formed a part, thus making the rise of the gates equal to the width, from centre to centre of the heel-posts, multiplied by 0.32958; or in round figures, when the rise was equal to one-third the span.

Hitherto no notice had been taken of the variations of stress due to the alteration of form when under pressure. Any analysis of such variations must necessarily be complicated; and it appeared to the author that it would be useless to attempt to arrive at any general form for such investigation, as every gate would have its own individual peculiarities, which would inevitably vitiate the result. Practically, if the strength of a gate was calculated on the bases of the extreme cases of nipping at the inner and outer edges of the mitre-post, the increased stresses due to alteration of form under pressure might be safely ignored. Setting aside theory, it must be remembered that the most economical was not necessarily the most advisable form for a pair of dock gates. The gate was the most important part of a dock, but it was a comparatively small item of the cost, and its outlines should be designed with a view to the general convenience

and requirements of the situation, rather than to the structural economy of the gate itself.

The paper was accompanied by four appendices. The first appendix gave a method of dividing the vertical section of a gate into layers sustaining equal pressure. The second was a proof of one of the investigations in the paper. The third gave an example showing the practical application of the method of ascertaining the stresses on a dock gate; and the fourth treated of the deflection of wooden beams of uniform rectangular section throughout their length, and showed how the deflection could be deduced from the curve of bending moments.

THE BATH AND WEST OF ENGLAND SOCIETY'S EXHIBITION AT EXETER.

ESTABLISHED IN 1777 at Bath, this society's annual exhibitions held high prestige in the western and midland counties. The show for 1879 has just been held at Exeter, opening upon the 2nd, and closing this day (the 6th inst.) The weather was most unpropitious; but notwithstanding the vagaries of the elements, the ancient city has been thronged throughout the week with visitors. The streets have been bedecked most gaily with arches and flags, and illuminations have taken place every night. The exhibition itself was held upon grounds adjoining the Topsham-road Barracks, a space some 600 yards by 300 yards being inclosed by boardings. Within this were some 40 or 50 sheds. The fine-art display has exceeded, perhaps, in merit, the displays of past years. The principal loan contributors were Sir Stafford Northcote, Sir Thomas Ackland, Lady Morley, Lady Rolle, Sir John W. Walrond, &c., and some of the pictures shown were very fine. There were three valuable examples of Gainsborough—a portrait of Mrs. Cleveland, wife of John Cleveland, Esq., M.P. for Barnstable in seven successive Parliaments; a portrait of Richard Stevens, Esq., of Winscott, Sheriff of Devon in 1737; and the third is a portrait of David Garrick. Mr. J. C. Moore-Stevens has in a case close by, in reference to these pictures, three letters of Gainsborough's. One is written from "Circus, Bath, Sept. 13, 1767"; another is dated, "Bath, Jan. 28, 1768"; and a postscript is added to the third, dated Oct. 2, 1767: "P.S.—Packing case cost me 7 shillings, which my wife desires me always to remember, and I often forget voluntarily, because I am ashamed to mention it." There was a masterly portrait of "James Northcote, R.A.," by himself.

Amongst the water-colours were a series of clever sketches from Brittany, Normandy, and the Rhine, by Mr. R. Medley Fulford, architect. There was also an interesting collection of old china, Bow, Chelsea, Derby, Worcester, Bristol, Swansea, and Wedgwood ware; and some rare and curious old Liverpool painted tiles. The display of lace was excellent, Miss C. B. Cossins, of Broadgate, Exeter, made a good show of charming specimens of Honiton lace, and a woman working at the "pillow" by her side illustrated pleasantly how this much-prized (and priced) material is manipulated. But the richest collection in this class was shown by Messrs. Tucker and Sons, of High-street, Exeter, who, in a small case of Sage's, Gray's-inn-lane, having a frontage of 6ft. by 5ft., contrived to exhibit nearly £2,000 worth of this delicate fabric. Small Point Gaze collars at five and six guineas apiece; pocket-handkerchiefs at fourteen guineas apiece; and "flouncies" of the same material at 58, 150, and 180 guineas each respectively, suggested seriously to the very much married man of the period that fair women sometimes put more than the yearly stipend of a curate upon the very hem of their garments. Mr. Harry Hems, of Exeter, exhibited a number of examples of his church furniture and carved work, amongst them an eagle lectern designed by Messrs. Innocent and Brown, of Sheffield; and there was a good show, principally by local cabinetmakers, of so-called "Early English," or "14th-century" cabinets—their style really being a free treatment of Jacobean work. Messrs. W. Easton and Son, granite merchants, &c., of Exeter, showed a comprehensive collection of geological polished specimens illustrative of the marbles and granites of Devon, and worked blocks of their Haytor, Moreton, Hampstead, and Dartmoor granites. They also showed a good grooved granite roller clod-crusher. Messrs. Candy and Co., of Cludleigh-road,

Newton Abbot, had samples of their excellent tiles, bricks, and Doulton ware; and Mr. John Matthews, of Weston-super-Mare, showed good specimens of what his warm and red clay was capable of doing in the way of vases, stands, drain-pipes, &c., &c. What may be done in the way of improved greenhouses was pleasantly illustrated by erections upon the grounds by Messrs. Cranston and Luck, of Highgate-street, Birmingham, and others.

In wood-working machinery the largest show was made by Mr. F. W. Reynolds and Co., of Southwark-street, S.E. This energetic firm had 29 band and circular saws working upon the ground, and their new mortising, boring, core-driving, and tenoning machine received special attention from those interested in the building trade. Great complaints were made generally of the traction-engines being allowed to come upon the ground up to the very last moment, tearing up the turf and helping to make the mud altogether dreadful.

LIGHTNING CONDUCTORS.

IN some recent accounts of damage done to the church of Laughton-en-le-Morthen, it was stated to be protected by a lightning conductor. From the description of the damage done to the building, Mr. R. S. Newall came to the conclusion that there was no efficient conductor, so he had it examined, and the following is the result:—The spire is 175ft. in height, and it had attached to it a thin tube, made of corrugated copper, about seven-eighths of an inch in external diameter and five-eighths internal. The copper is about 1-32nd of an inch in thickness, and it weighs about 1½lb. per yard. It is made in short lengths, joined together by screws and coupling pieces, but there is no metallic contact whatever between the pieces, which are much corroded. The conductor appeared to be fastened to the vane. It was not in contact with the building, which it ought to have been, but it was kept at a distance of about 2½in. from it by 21 insulators. The earth contact was obtained by bending the tube and burying it in the ground at a depth of from 6in. to 18in., the soil being dry loose rubbish; the length of the earth end was only 3ft., with two short pieces of about a foot in length, each tied to the tube by thin wires, thus forming altogether a most inefficient conductor. It was placed in a corner formed by a double stone buttress, which came between the conductor and a lead-covered roof attached to the spire, the distance between the conductor and the lead roof being about 6ft. 6in. The lightning appears to have come down the conductor a certain distance, and, finding the road to earth bad, it passed through a buttress, dislodging about two cart-loads of stone, and then came down the cast-iron down pipes, leading from the lead-covered roof, and so to earth. Now if the conductor had been made of copper-wire rope, weighing about 2lb. per yard, and fixed in contact with the spire, without insulators and with a proper earth contact, no damage whatever would have been sustained by the building; and if the conductor had been tested periodically by an expert he would have shown whether the conductor was good or useless. This examination ought to be insisted on, as the earth connection is often wilfully destroyed; but Mr. Newall states he has never in all his experience known a building which had a conductor properly fixed to suffer damage from lightning.

The Chapel of Ease of St. John, at Needham Market, Suffolk, which is practically the parish church of that town of 1,500 inhabitants, was closed at short notice on the Sunday after Ascension, the architect who had been consulted, Mr. J. H. Hakewill, having certified that the roof is so unsafe that it may suddenly fall. A meeting was held to consider the matter on Friday last, when it was reported by Mr. Hakewill, that some of the roof timbers are broken and others rotten, and although the walls are sound, lining after lining has been added to the roof, till its weight would drive out the stoutest nail. Behind the ceiling it has been found is a handsome timber roof of 15th Century date, almost unique in construction and beauty, and the question came up whether this should be restored or a simple plain roof erected at small cost. After discussion it was resolved to carry out the scheme of restoration as originally proposed in its entirety, and in sections, the roof being first, the seating second, the bellcot third, then the porch, and lastly, the external walls and windows.

PROPOSED RECASTING OF CHURCH OF ST. MARY, WOOLWICH.—DETAILS OF NEW CATHEDRAL AT MELBOURNE.—DESIGN FOR A COUNTRY HOUSE.—ORNAMENT FROM AMIENS AND SALISBURY CATHEDRALS.—CLAREMONT BUILDINGS, HASTINGS.

OUR LITHOGRAPHIC ILLUSTRATIONS

CHURCH OF ST. MARY, WOOLWICH.

It is proposed to remodel this unsightly structure by replacing the present flat entablature and low ceiling, with an arcade, supporting a "barrel" roof, adding greatly to the height of the church. A chancel, with an apsidal end, is intended in lieu of the existing shallow recess for the Communion-table. The interior is designed to be coloured throughout. An open belfry is proposed, in place of the present ugly cornice and parapet. The architects are Mr. E. F. C. Clarke and Mr. George Wood, of 10, Serjeant's-inn, Fleet-street.

NEW CATHEDRAL, MELBOURNE.

On May 16th we illustrated in full the several elevations with plan of this important building, which is about to be erected at Melbourne, from the designs of Mr. W. Butterfield, architect. To-day, in obedience to our promise, we publish longitudinal and other sections, rendering our series of illustrations of the design thoroughly complete. The characteristic refinement of the design and purity of its detail is well worthy of the reputation of the eminent architect who is the author of the design.

DESIGN FOR A COUNTRY HOUSE.

The accompanying drawing illustrates a country house designed by Mr. J. D. Sedding. The style employed in the design is that of the 16th Century, and it is intended to be built partly of red brick and partly of wood and plaster work.

ORNAMENT FROM AMIENS AND SALISBURY CATHEDRALS.

The Royal Architectural Museum Sketching Club held its monthly meeting at Westminster, on Wednesday last, the members assembling more numerous than on any previous occasion since the commencement. Mr. Ewan Christian was to have been the visitor on the occasion, but was unavoidably prevented from attending. Several sketches of much merit were brought together, and mutual criticisms made. To-day we publish one of the drawings submitted at a recent meeting, by Mr. J. Frederick Pennington. The sheet illustrates to scale some very interesting ornament from Amiens and Salisbury Cathedrals of Late character. On Saturday, the 14th inst., the first of a short series of Saturday

afternoon sketching excursions, arranged for members of the club, will take place under the direction of Mr. Maurice B. Adams, to Stone Church, Kent, where the rector, Canon Murray, has kindly promised to meet the party. Mr. Randall Druce, curator to the museum, is the hon. sec. of the Sketching Club, from whom particulars may be obtained.

CLAREMONT BUILDINGS, HASTINGS.

THE above buildings have been erected at the sole cost of Thomas Brassey, Esq., M.P., for the benefit of the town of Hastings and St. Leonards. The top floor consists of a series of well-lighted rooms, and are used exclusively by the School of Art and Science. The second floor contains studios, and a suite of apartments for Mr. Brassey's accommodation. The first floor is used for public meetings and exhibits of paintings, &c. The ground floor is fitted as a library and mechanics' institute. The basement is used by the Hastings Rowing Club, both for club purposes and the stowage of boats, living-rooms being also provided for the housekeeper. Mr. W. L. Vernon is the architect.

EDWARDS'S VENTILATOR AND SASH FASTENER.

ONE of the cheapest, most easily managed, and effective sash fasteners we have seen is that invented by Mr. G. Edwards, of Brompton-road, the principle of which will readily be understood from the sketch. By pulling two handles the fastener is unlocked and the top sash lowered; by pulling two others the window is at once closed and locked so that it is impossible to open it from the outside. The sash can remain open at any height, so that any desired amount of air can be admitted. The fastener can be easily applied to any window with a sliding sash, it does not interfere with the action of Venetian or other blinds, it is self-acting in so far that the window locks itself when wholly or partially closed, and both sashes are closed simultaneously; it is also unlocked and opened at the same time. The best proofs of its security against burglars and breakage of the window-glass are that the Metropolitan Police recommend it as the best protection for windows, and that plate-glass windows fitted with the fastener are insured at a considerably reduced premium.

The best proofs of its security against burglars and breakage of the window-glass are that the Metropolitan Police recommend it as the best protection for windows, and that plate-glass windows fitted with the fastener are insured at a considerably reduced premium.

THE DECORATION OF ST. PAUL'S.

THE attention of the artistic community in Florence has been called to a proposed contribution towards the solution of the problem how to complete St. Paul's Cathedral, in the shape of a suggestive design for the decoration of the interior of the dome, the joint work of Charles Heath Wilson and R. Popplewell Pullan, the well-known architect. Messrs. Pullan and Wilson have for many years, each in his own way, made a special study of archi-

tectural decoration, and the principle to which they adhere, and of which their design is an exemplification, is that in all such work the architectural unity should be made the *sine qua non* of the employment of pictorial appliances, and that the painting or sculpture should distinctly be conformed to the architectural composition. The theme chosen by Messrs. Pullan and Wilson is the *Te Deum*. The dome is divided into eight sections by broad decorative ribs, painted and moulded, and the rib panels filled with arabesques in monochrome. At the bases of the ribs are eight thrones, on which are seated as many prophets. The thrones are architecturally designed, with cornices, pilasters, and niches. Over the cornice of each, to carry the human element into even the design of the ribs, stands an angel erect. The ribs terminate at their summits in foliated capitals united by arches, surmounted by frieze and cornice with pendentives. Between these ribs an architectural composition runs round the dome to support, divide, and facilitate the grouping of the human and angelic figures which form the dominant element of the entire design. The Evangelists that already occupy the spandrels will be included in this plan. The dado contains a decorative design, and in the podium above it are ranged the martyrs, the drum or tribune, as it is here called, beneath the dome not being included in the present design; but, if this were accepted, it is proposed to include the drum in the system and arrange it with a series of men of all nations representing the Church—"The holy Church throughout all the world doth acknowledge Thee." Then would come the martyrs—"The noble army of martyrs praise Thee." In the colonnade above the podium are eight Apostles, each (omitting the Evangelists already there) under a baldachin and seated on a throne, continuing the theme—"The glorious company of the Apostles praise Thee;" and above the architecture the hollow space of the true dome contains figures of angels rising and vanishing in space, and still above them, around and beneath the lantern, are cherubim and seraphim, while in the cupola of the lantern is the Lamb. The design prepared by Messrs. Wilson and Pullan is of one section, the eighth of the project, and the figures are intentionally borrowed from the best known representations of the old masters, it not being their intention to suggest them as the designs for the individual figures, which will be left to the artists charged with carrying out the suggestion contained in the illustration of the *Te Deum*. It is said to be the intention of the artists to send the design to London shortly, in order to offer it for the consideration of the committee for the completion of St. Paul's.

JOHNSON'S CLIMAX DOVETAIL RECESSED BRICKS.

MR. A. JOHNSON, of Handsworth, has patented an invention which will save time and trouble, and avoid damage to walls in the fixing of woodwork. The idea consists in the manufacture of bricks with dovetail recesses for the reception of wooden pads to which may readily be secured door-jambs, casings, skirtings, cornices, angle staffs, architraves, shelving bearers, shop fixtures, boarding, or any other kind of woodwork. The recesses are of varying sizes and forms to suit the different classes of work intended to be fastened to the pads inserted in them. By the adoption of the invention which is inexpensive in its application, all necessity for plugging is avoided, the work can be fixed truer, time, labour, and nails will be economised, and all cutting of brickwork avoided. Several large brickmakers have already obtained licenses of the inventor for the manufacture of the recessed bricks, which we have little doubt will soon come into general use.

COMPETITIONS.

BIRMINGHAM.—About forty-six sets of plans have been received of the Wesleyan Memorial Building, in Bishopsgate-street, for the intended Wesleyan College at Birmingham. The committee have not yet made a formal inspection of the drawings, but will meet on the 12th inst. to consider the matter. Mr. Alfred Waterhouse, A.R.A., has been retained to assist in making an award of the premiums, and in selecting a design for execution.

THE CITY OF LONDON SCHOOL COMPETITION.

A STRANGE reticence has been observed by the City of London School Committee in respect of the designs submitted in competition for the new building on the Thames Embankment, and this reserve is all the more inexplicable when we contrast it with the action of other public bodies. Indeed, we do not see what object—except, indeed, a sinister one—can be gained by maintaining such secrecy respecting the action of the committee in the selection of the premiated plans; certainly, at least, there can be no sufficient justification for shutting out the professional press from a view of the designs. Our own knowledge of many of the designs that have been submitted, and a brief inspection of them, at No. 17, Aldermanbury, where they are at present looked up from view, enable us to say that a few clever plans have been sent in out of the 53 sets submitted, several of the authors being very well-known men. Out of these the sub-committee have, we understand, selected for consideration the designs submitted under the mottoes "Live and Learn," "Simplicity," and "Playground," and we further believe that at the meeting of the committee on Wednesday it was decided to place "Live and Learn" first. The drawings have been arranged on screens in bays, round a central lighted wall space of the empty warehouse in Aldermanbury, and occupy the whole of the first-floor, and, as far as lighting and accommodation is concerned, the building affords every convenience for a more public display. The site chosen by the Committee for the New Schools adjoins De Keyser's hotel, and has a frontage towards the Embankment of about 180ft., and a depth of about 320ft. On the west and north it will be bounded by two proposed roadways. The shape of the land is nearly rectangular, and a main front and side entrance have been provided in most of the plans. Among the instructions were a few conditions of importance. Twenty class-rooms had to be provided, each to hold forty boys, with a cloak-room attached; the cubic space of air was to be a minimum of 140ft. per boy, and some of the class-rooms had to be arranged in pairs; a hall for general purposes, distributions, &c., to hold 1,000, had to be provided; a dining-room for 200 boys, capable of sub-division into four separate rooms; a lecture-room on the top floor, besides laboratory, class-room for chemistry, playground, &c. Three premiums of £300, £200, and £100 were to be awarded to the three selected designs.

From a general survey of the plans, the authors appear to have adopted either a symmetric or an irregular disposition of the parts, and they may be roughly divided into those having a central hall or assembly-room, and those with a more or less one-sided arrangement. The former are the more numerous. The larger number of drawings show a rectangular arrangement; that is to say, the plan more or less fills up the site, and in many instances to the obvious loss of playground area, which should be a matter of primary importance in the selection of a design. We observe that the favourite idea is to place the assembly-hall in the centre, round which are the corridors and class-rooms, the official or secretaries' and masters' rooms being located in the front. This is, without doubt, a very obvious principle of planning, and would strike one as the easiest mode of arranging the accommodation; but there are certain serious objections in the way of many of the suggested arrangements on this principle that strike us. One is the area taken up, the awkward means of exit provided for the pupils when leaving the hall for their respective class-rooms—tending to interference or confusion, and

the want of general supervision and lighting. As regards the last very important condition, in many cases the light to hall is obtained above the class-rooms, either by a clerestory or from the roof, while the class-rooms are lighted separately from the sides or from skylights. The central, quadrangular hall arrangement has been followed by many of the competitors, who, to all appearance, have scarcely solved the above difficulties, while the provision of staircases, in some instances, is certainly defective. Touching the entrances, too much importance cannot be attached to a direct passage from the main Embankment entrance to the hall, and so as to avoid any contact with the officials and masters. The hall, intended to seat 1,000 persons, has been variously computed, but the main consideration should be a good shape to aid general supervision by the masters, and also for sound. Some of the plans by their mode of seating ignore these considerations, though they generally appear to show ample lighting. The class-rooms should be grouped round the hall, be well lighted, either from the left-hand side of the pupil or from top lights, and should each have its separate lobby for hats, &c. Another point is the proper position for the lavatories and closets; in some instances these are inadequate or badly placed, and it is requisite that at least two sets, one on each side of the hall, should be provided. The head master's room and class-room ought to be in proximity, if not in direct communication; the dining-room should be conveniently placed, in connection with the chief corridor; and the laboratory and chemical department communicating, but in some part of the building removed from the class-rooms and the risk of accident. Lastly, the cooking department should be either above or below the dining-hall; the former is the more desirable position for it. A few of the competitors have adopted a circular end to the assembly hall, but the radiating principle of disposing the class-rooms has been adopted in one instance, by the author of the design marked "Blackfriars." This competitor has a semi-circular plan of hall with radiating passages and seats, the platform being placed in the centre of the straight side. Round the outer periphery of the hall is a wide corridor which gives access to seven class-rooms, each 20ft. square, lighted on the outside and separated by cloak-rooms. Direct access is thus obtained from the radiating passages of the hall to the class-rooms. At the angles of the semicircular corridor with the front range are the staircases leading to the upper floors with lavatories, &c., behind, and these are connected with the principal entrance by a straight corridor, from which the master's, assistant-master's, secretary's, and other official rooms in front are entered. On the first floor the class-rooms are continued, the front block having four arranged in pairs by sliding-doors suitable for special classes, such as drawing. All the class-rooms, twenty in number, are placed on the ground and first floors, the upper floor in front being devoted to a central natural science lecture-hall, over entrance with the chemical department on the west, and the cooking department on the east. The hall is lighted by clerestory windows and from the roof. The Embankment façade, of three stories, broken by a bold central projection in three bays, and by end wings, and is in the Renaissance style; there is an ample playground in the rear, and the cost is estimated at £48,500. The author sends an alternative plan, showing a rectangular hall. We note three designs in which the rectangular plan has been adopted with more or less success. In style, the architects have generally taken some version of Classic for their design. We note a few of Italian and Queen Anne character, and one rather striking example of the latter style shows the

front broken by a series of flat mullioned windows, with gables, with a rather queerly-shaped tower on the eastern return, and a considerable breaking back of the façade. The author whose motto is "Concentration," and who has a large hall 123ft. by 64ft., surrounded by an open arched corridor, has cleverly managed to bring in the dome of St. Paul's and St. Bride's steeple as a help in balancing his composition. Thirteenth Gothic is not unrepresented; for instance, there is a well studied design by one of the leading Gothicists, in which the front hall is made to play an important part in the elevation, and another design in a later type by the architect of one of our large public City schools. We hope to be able to give some further particulars shortly.

AN ARCHITECTURAL EXCURSION AT STAMFORD.

A JOINT meeting of the Lincoln, Northampton, and Leicester Architectural Societies was held in Stamford last Wednesday and Thursday week. After attending morning prayer at St. Mary's Church, the edifice was examined. An excursion round the town was then made. With regard to an interesting cellar on St. Mary's-hill, Mr. Fowler remarked that it had been longer than it now is, and was of about the date 1200. Precentor Venables said in olden times it was usual to build large houses on vaulted cellars. The remains of the Manor Court were next inspected. The party then climbed the Castle-hill, where the Rev. C. Nevinson gave a history of the stronghold. Browne's Hospital was next visited, and it and its curious contents afforded considerable gratification. Mr. Neale said the stained glass there would stand first in the country of its date; the handling and colour were excellent. An interesting cellar under the Red Lion Inn, which has stone vaulting with somewhat thin and chamfered ribs, and which is said to be early 15th century work, was inspected; and the party then went to the house opposite the Conduit, lately occupied by Mrs. Bishop; the date of an arch there, the existence of which appeared to have been unknown to many of the townspeople, was referred by Mr. Neale to about the year 1200, the interesting capital affording very good testimony. St. Leonard's Priory was much admired, and the critics were deeply interested in the several gradual transitions met with in the north arcade and the west front. The shafts and capitals of the latter were assigned to about A.D. 1200. At St. George's Mr. Neale entered into the oft-discussed question of certain piers in the north arcade; differing from the Rev. G. Ayliffe Poole, he believed that the circular and the octagonal parts had all been built up in proper gradation, and as now shown. The window of the tower was the only Decorated one in the town. There was nothing peculiar about the tower except its ugliness, i.e., it was oblong. Some of the glass in the south wall of the chancel was as good as that at Browne's Hospital, which was saying a great deal.—The visitors then repaired to the Assembly rooms for luncheon.—In the evening a meeting was held in the Assembly-rooms; the Bishop presided. The Bishop advocated the foundation of a county museum. The Rev. G. A. Poole read a paper with the title "Fragments of Diocesan History in the time of Charles I. and Charles II.," in which he described the troubles of the clergy in the Peterboro' diocese during those times of civil strife. Mr. Neale, F.S.A., followed with a paper on "St. Martin's and St. Mary's churches," in which he let the stones tell their own history. He suggested that at St. Martin's there should be a record stating where much of the very fine glass came from. Referring to the west door of St. Mary's, Mr. Neale differed from other writers, and gave reasons for believing that the pointed arch and the semi-circular one beneath it are the work of the same architect. He suggested that the tower be opened out into the church. On the following day, the party visited Ketton, North Luffenham, Exton, Empingham, and Tickencote.

The coffer-dam at the new dry docks now in course of construction at Southampton gave way on Monday night.

OUR COMMONPLACE COLUMN.

GREENSAND.

THE name is given to two divisions of the Cretaceous measures, so-called from the green specks of silicate of iron sometimes formed in the beds, and which give them a green colour. The Upper Greensand consists of beds of sand, generally of a green colour, with masses of calcareous grit called firestone. The strata in the cliffs of the Isle of Wight are of considerable thickness. The Lower Greensand consists of a large series of indurated sandstones and clays, with occasional calcareous beds. The sands preponderate in the Upper and the clays in the Lower portion. The calcareous stone is called Kentish Rag, and is much used for building in Kent and Sussex. It is a highly fossiliferous limestone.

GRIDIRON.

A gridiron is used in Christian art as a symbol of St. Lawrence, Deacon and Martyr. He is usually represented as holding it in his hand, on account of his having been martyred upon one. Sometimes, however, this utensil is symbolical of St. Faith. A gridiron with spikes is symbolical of St. Vincent, the instrument of his torture.

GRIFFIN.

Griffin or gryphon (Gr. *γρυφός*, hook-nosed) is a mythic animal with the head and wings of an eagle combined with the body of a lion, symbolical of swiftness and strength. It is frequently found in Heraldry and Christian art. The earliest example of this animal, Fairholt says, is that on a bronze patera which the Samians ordered to be made about B.C., 640. In Christian art the griffin is symbolical of vigilance, and when found on tombs it is the guardian of the dead. M. de Caumont speaking of it that Pliny, who has been followed by the learned Mediaevalists, says that griffins are a kind of monster which dig up gold from the mines, and devote their whole strength to preserving it.—C. F. W.

GRILLES.

Grille enclosure screens to chapels and tombs are common, both in this country and in France. One of the best English examples is that round the tomb of Queen Eleanor, in Westminster Abbey. In France and Germany grilles are more numerous. Augsburg and Nuremberg are particularly rich in this kind of metal-work, in which scrollwork and crossbars, with sprays of foliage and geometrical forms appear. Seventeenth century examples of tomb grilles may be seen at Salzburg, in the cemetery of St. Peter. Generally grilles are of hammered iron, put together by rivets or clips, though in most of the best work riveting is more rarely used than welding. In the square-bar work the bars are halved and welded together, and in round-bar, eyes are formed, through which one of the stalks passes. In the former kind the diagonal bars are, in one direction, placed square, and in the other, edgewise, the latter passing through the former. For further information and detail, see the valuable paper by Mr. Penstone, in the BUILDING NEWS, p. 613, ante; also V. le Duc, *Dict. Rais.*, under "Grille."

GROIN.

Groin (Ice. *greina*, to divide) is the angle formed by an intersection of vaults (Parker). All the principal Gothic ceilings or roofs were groined. At first the groining was left plain, with merely the edges chamfered, as in the chapel of the Pix, Westminster Abbey (1060-1066). In Peterborough ribs are introduced. Moulded are also to be seen at Salisbury, Lincoln, and Durham Cathedrals, &c.

GROTESQUE.

A style of ornament which owes its name to the discoveries made in the baths of Titus and other Roman buildings in the 13th century from the Italian word "grotto," a subterranean chamber. In the Renaissance we find this kind of ornament much used. It abounds in transformations from the animal to the vegetable, and mingles in fantastic confusion all conceivable forms of nature. The Mediaeval artist delighted to indulge in compositions of the grotesque, as we find in carved capitals, bosses, string-courses, and carved work generally; he often made them suggestive of some quality, such as fierceness; generally these inventions were employed in the service of religion to create fear, and to embody the passions and vices of the world. We doubt

the value of them now, as they have lost their original intention, and it is at least open to question whether such repulsive creations as many of the latter are have a rightful place in architecture. See illustrations in BUILDING NEWS, also article on "Grotesque Animal Representations," p. 178, Vol. XXXV.

GROYNES.

These are small dykes to protect river banks, projected at right angles thereto. Professor Rankine, in his "Manual of Civil Engineering," says "each groyne protects a portion of the bank of about five times its own length, and usually causes the current that sweeps round its point to scoop out an excavation in the bottom of the channel of a breadth equal to about one-quarter of the length of the groyne, the material scooped out being deposited in the space between the groins." He adds they are injurious to the regularity of figure and stability of the bottom of the channel, and should only be used as a temporary expedient to protect the banks until better works can be completed. Groynes are constructed generally of loose stones, or of piles and planks, though concrete in blocks has been successfully used in protecting coasts exposed to a rough or heavy sea. At Brighton the timber groynes have been replaced by concrete blocks, and considerable accumulation has accrued by their adoption.

GULES.

A term used in heraldry for red. In print it is represented by parallel vertical lines covering the field, &c. In descriptions it is written gu. Mr. Boutell gives the following hints for its use in illuminating or blazoning. "Orange vermilion, either pure or mixed, with a very little cadmium yellow or Chinese white, and still less gum; shade with carmine, or crimson lake and gum."—C. F. W.

GUTTÆ.

Guttæ (*gutta*, a drop), small conical ornaments used in Doric architecture, beneath the mutules of the cornice, beneath the tenia of the architrave, and under the triglyphs (Parker). They are supposed to represent raindrops.

GUTTER.

A channel for water, as applied to buildings, is of great antiquity. The Greeks used gutters at the eaves of their buildings formed by hollowing out the corona or upper member of the cornice. The water was discharged through small openings or gargoyles in the shape of lions' heads.

Roman gutters were often formed by tiles in cement.

In the Middle Ages the water was collected in gutters behind the parapets and discharged through the buttress-heads or gargoyles in a number of small streams. Ultimately the use of lead pipes to carry the water direct to the ground superseded the gargoyle, and many tasteful heads to receive the water still exist of the 15th and 16th centuries. See Details of Lead-work, in Vol. XXXV., from Haddon Hall. The square form of pipe was common, and it has many recommendations in its favour, one being the capability of the pipe to expand during frost, and so preventing bursting, besides architectural reasons. For lead gutters 7lb. to 8lb. lead is necessary; they should have a current of at least $\frac{1}{4}$ th of an inch to the foot, though lin. in 10ft. is commonly allowed. At the backs of parapets and chimneys the lead should turn up against the wall 5in. to 8in., according to circumstances, depending upon exposure to wind and pitch of roof. The flashing or apron should be of the same width. In the measurement of gutters take the length of gutter by average width, state thickness of gutter-boards, and size of bearers distance apart. Lead boards are taken separately. The drips and cesspools are numbered. In roofs with projecting eaves the gutters are often sunk into them, and are called blind gutters.

GYMNASIUM.

A gymnasium (*γυμνασιον*) was, with the Greeks and Romans, a building for philosophers as well as youths, for the training of the mind as well as the body. They were first built about the time of Solon. Grammar, music and gymnastics constituted the whole course of a Grecian youth's education, so that this last was held in very high regard. They held that a *mens sana* must be accompanied with a *corpus sanum*. It was in the gymnasium that Greek artists learnt that know-

ledge of the human form which they sculptured with such exquisite proportion. The celebrated baths of Caracalla included gymnasias, stadia, temples, academics, lecture-rooms, &c. It should be noted that the Germans use the term gymnasium for "mental schools, preserving in part the old classic meaning, whereas an Englishman by the same term always means a school for bodily exercise." (See Smith's "Dict. of Antiq.")—C. F. W.

GYMNECEUM.

Gymneceum (*γυμναστήριον*), the women's apartments. In a Greek house the men's apartments were always in the front, and the women's behind, rarely on an upper story.—C. F. W.

HAGIOSCOPE, OR SQUINT.

Oblique openings or slits pierced generally in the walls or jambs of the chancel arch, intended to give a view of the high altar to those seated at the east end of the aisles or chapels. These openings were sometimes arched and cusped. Their most important use was doubtless to enable the acolyte appointed to ring the sanctus bell to see the performance of high mass, and to ring it at the proper time. The English form of the word "squin" is far more appropriate than the Greek one of hagioscope as applied to a Mediaeval building. This feature, according to Parker, abounds in the neighbourhood of Tenby in South Wales, though examples occur at Haseley, Oxon, Chipping Norton, Crawley Church, Hants, Bridgwater Church, &c. The same authority says they are usually about a yard high, and about 2ft. wide, often wider at the west end. They occur in other situations, but always in the direction of the high altar. See illustrations in Parker's Glossary.

HEXPARTITE.

A species of groining where each bay is divided into six parts, instead of the commoner division of four, and where the diagonal ribs embrace two bays of cross vaults. The crowns of vaults

of this kind are not always level, but have a slight rise, so that they partake of a domical character. The choir of Canterbury has this description of vaulting.

HALL.

French *salle*, *salon*. This was the principal apartment in the Middle-Age dwelling. In the Norman castle the hall was generally in the keep above the ground floor, though in later examples they are chiefly on the ground floor, as at Westminster. There was a hall and one "solar" or sleeping apartment, and this arrangement prevailed with slight modifications during the 12th and 13th centuries. At the end of hall was the daie, on which the lord of the manor had his table and entertained his honoured guests who sat with him; his retainers sitting at another table in the lower part of hall. The hall was a characteristic feature of the feudal system of building, and when that system died out the large common hall was lost in other and more numerous apartments. The roofs especially were very handsome and richly carved, as those that still exist bear witness. We may mention those of Guestion Hall, and the Priory Rectory, Malvern, as choice instances. Examples are to be met with in many counties of England; the best known are Westminster, Guildhall, Crosby Hall, those of the Inns of Court, Hampton Court, Eltham, Ightham, Kent; Mayfield, Sussex; Guestion Hall, Worcester; Great Malvern Priory, Cobham, Kent. In some halls, bay windows are formed at the ends of the daie, and this feature is to be observed at Hampton Court.

For details of hall see "Dollman's Analysis of Ancient Domestic Architecture"; "Parker's Domestic Architecture," &c.

Many fine halls were visited by the Royal Archaeological Institute last year (1878) in the neighbourhood of Northampton, fully described

in our reports of that visit (see page 127, Vol. XXXV.), such as Rushton Hall, Kirby Hall, &c. Illustrations of many will be found in back volumes. See also correspondence touching Wollaton Hall, p. 712.

MUSIC HALLS.

For proportions of great music halls we refer the reader to the "Dictionary of Architecture," also to page 611, Vol. XXXIII.

THE INFLUENCE OF ROUGHNESS ON THE FLOW OF WATER IN PIPES.

THE literature of practical hydraulics is yearly becoming so voluminous that the engineer will be glad to have recourse to tables prepared for him, upon which he can place reliance without the trouble of working out for himself theoretical formula. An immense deal of labour and thought has been spent in the search for a mathematical expression for the value of the mean velocity of a stream of water; but such labour has been only of approximate value, and that under certain conditions, for it is evident a formula applicable to large channels and rivers would be useless for pipes, and a formula for a rough channel would be equally inapplicable to one of a smooth perimeter. Du Buat had considered that the velocity was quite independent of the material forming the perimeter, whereas the experiments of Kutter, D'Arcy, and others, have recently shown that the degree of roughness has much to do with the velocity. Kutter published a new formula, which has been translated by L. D'A. Jackson in a recent work noticed by us at the time, and as the formula was too complicated for general use, a diagram was shown that could be made applicable to both large rivers and small channels. Mr. R. Hering, C.E., in a paper on "The Flow of Water in Small Channels," in the *Transactions of the American Society of Civil Engineers*, shows a modification of Kutter's diagram which obviates the inconvenience attending the use of it, and Jackson's translation, which was found too small for accuracy. In this diagram, the relations are obtained in English measures between the mean velocity (v), Kutter's coefficients (c), the mean hydraulic radius (R), the roughness of wetted perimeter (n), and the slope of the water surface (s); a vertical axis has the coefficients c graduated on the left with the grades in feet per 100 on the right side; the horizontal axis has the mean radius marked above, and the mean velocity in feet per second below. To the left are formed hyperbolic curves indicating grades from zero to 0.4 per hundred. Degrees of roughness, from planned timber to stony soil and channels impeded by detritus and vegetation, are shown by radiating lines from a certain point obtained by experience and cross the curves. Cement, plaster, rough timber, and brick materials used for lining sewers are thus shown. By this simple diagram, containing the relations of the principal quantities in a practical form, the separate values of any one can be obtained by a simple operation, which, without a diagram it would be of little use to explain here. For more convenient use, a series of graphical tables is added, developed from the relationship existing between the five quantities above enumerated. These are constructed on cross section paper noting the grades along the top, and the discharges along the side, and are confined to circular and egg-shaped sections calculated for three values of (n), or roughness. These graphical tables are very convenient for practical purposes, while they are quite accurate enough for all ordinary requirements. The writer observes, "All the known elements occurring in the problem of the flow of water in small channels, giving the results in conformity with the formula of Ganguillet and Kutter can therefore be arranged in a convenient and practical form. The diagram will give the values of v , n , c , and g in a few moments, and the tables prepared for special shapes of water section will give the size and discharge at a glance, and by examining the effects of slight variations of size or grade, will enable the engineer easily to determine the most economical design." Three diagrams are added to prove the influence of roughness upon the discharge, and that the effect increases with the smoothness of the wetted perimeter, and inversely as the size, so that "the smaller the channel the better it will pay to increase the degree of smoothness to its highest practical limit." To take one instance given, an open circular channel 3ft. diameter, at

a grade of 1ft per hundred when built of rough rubble, shows a mean velocity of 6.2ft. per second, but when carefully plastered with pure cement, or with a thick coat of natural asphalt, it will give a velocity of 13ft. per second, or more than double the discharge. From the results thus obtained, the value of smooth glazed stoneware pipes, or asphalted pipes, is placed beyond doubt particularly for small sewers, and we have a further proof of the advantages of truly laid pipes. To show the practical use of the plotted tables we have been referring to, let us take another instance. Given 500 acres to be drained of an inch rainfall, the available grade being 0.3 per 100. We require to know the diameter of a circular brick-built sewer. Referring to plate IV., we find the horizontal line indicating the discharge of 500 cubic feet (being equivalent to the drainage of 500 acres), and where this intersects the vertical ordinate indicating grade, we read on the radiating line the required diameter of 8ft. and a velocity of 10ft. per second. We cannot devote more space to the subject, but recommend Mr. Hering's paper and graphical tables to the attention of all interested in drainage.

HINDLE'S PATENT ASHLAR CONCRETE.

A NEW patented system of concrete building has been brought to our notice in a pamphlet under the above title. The patentee, Mr. Thomas Hindle, of Liverpool, to use his own words "unites the block and monolithic systems of concrete construction" by which it is claimed that the difficulties attendant upon each of these modes are removed and contraction avoided. The plan, from the description given of it, is certainly very simple: it consists of concrete blocks or slabs suitable for every kind of construction, such as for sewers, walls for gasometers, reservoirs, sea and retaining walls, house building, &c. The "slab" is in ashlar about 2in. thick, and can be made of any length and depth, while the "block" is thicker and can also be formed to any dimensions. The slabs or blocks are made in moulds with a bevelled sinking or groove on each edge of the block, which when put together are filled up, making a homogeneous facing. For cottages slabs $1\frac{1}{2}$ to $1\frac{3}{4}$ in. are recommended, with one tie or bond to every superficial yard, and for all partition walls blocks three or four inches thick. The illustrations given—by the way, rather badly drawn—show walls built hollow of these slabs, the inside being filled with rough concrete. Walls to imitate stone ashlar with grooved joints and rusticated quoins, gate piers, and window dressings, are illustrated to show the application of the material, but we regret a more original adaptation has not been aimed at. The cost of a yard super of a 4in. wall is estimated at 2s. 5d., or at £11 1s. 1d. per rod; that of a 9in. wall, 4s. 2d., or £9s. 9s. per rod, and of a $1\frac{1}{2}$ brick wall 5s. 10d., or £8 16s. 6d. per rod. These prices allow for concrete to cost 5d. per cubic foot, and for making, erecting, and filling in the hollow. Mr. Hindle's system dispenses with costly appliances; it adopts a reasonable mode of wall construction not open to the objections of the monolithic or filling-in systems, and we can recommend it to the attention of builders where the manufacture of concrete can be carried on economically. The system is being worked by Mr. Samuel Vestey, of 5, Matthew-street, Liverpool.

THE YORK FINE ART AND INDUSTRIAL EXHIBITION.

I SEND the following in continuation of my notes printed on p. 568:—In the South Gallery the exhibits are now *in situ*. Mr. C. Green, of Sheffield, has various articles in which moulded bronze panels form the chief feature. The large ebony cabinet is especially worth attention; and the bronze panels, three with child figures in full relief, are excellent. Yates and Co., Wilton, have a hand-made Saxony carpet in blue and green, and a real Axminster of less conventional pattern. The productions of Mr. Snowdon, Rochdale, are conspicuous for the excellence of workmanship, the designs being mostly very simple. The bed-room suite in sycamore, with mouldings in walnut, is quiet and altogether pleasing. The exhibits of Roodhouse and Sons, Leeds, also deserve a good position. The bed-room suite is Anglo-Japanesque in design, that of the dining-room Jacobean.

The bed-room suite of Isaac Brown, York, is very simply treated, the only ornamentation being in lines of inlaid wood, white and black triangles alternately. The bed hangings, yellow ground, are rich in appearance, but scarcely harmonise with the material of the furniture.

Before leaving the galleries, I must allude to the show-cases, which are all of a commonplace character, and are mostly finished off at top with brown paper or plain deal, although they are as much seen from above as from the sides. Under the North Gallery Messrs. Barrett and Leggott, Bradford, have several chimney-pieces, with grates, fenders, and fittings complete. One chimney-piece is of polished oak, simple and chaste in design; another is of white marble, and is suited for the drawing-room of a noble mansion; the dogs and fender are brass; the next is in black marble, of a bold Renaissance design. The middle panels (bronze) of the canted sides have female figures in full relief under alcoves; while excellently-modelled nude male figures, in positions reminding one of Michael Angelo, guard the fire-gods. Above the shelf is a large mirror in substantial, well-designed oak frame, with segmental pediment top, and side shelves for the display of vases. The designs of these chimney-pieces are superior to those which obtained a medal at Leeds in 1875, if we may judge from the drawings exhibited. Rowntree and Sons, Scarborough, are represented by a buffet in light, unpolished oak, a butler's sideboard, and dining-room chair in the same material. Colman and Glendenning exhibit specimens of their desks of various designs and all very good. Robson and Sons, Newcastle, have a bed-room suite in mahogany, and, like Messrs. Ogden, have chosen carpets and hangings to help the effect. The chair-seats are too light in colour. Messrs. Jones and Willis have a good show of ecclesiastical work, including a large and elaborate candelabra and a brass eagle lectern: the chief interest centres in the reredos of Flamboyant Gothic design, in light oak and many other woods, with pierced panels in walnut. The centre recess has an ogee cusped canopy. High up are two small figures of St. George and St. Denis. This reredos was made for the Paris Exhibition, and was designed by Mr. Scott Champion. The altar frontal is in the same style, and elaborately embroidered by hand. The ground work is white figured silk; in the centre quarterfoil, upon a back-ground of blue, is the figure of our Lord holding a golden sceptre. The super-frontal is of rich crimson velvet. The altar furniture, gas brackets, and other articles fully sustain the high reputation of the firm. I had almost forgotten the Sunbury Wall Decoration, with which several of the compartments occupied by furniture are lined with exceedingly good effect.

C. P. E.

ART FURNITURE.—A GRAND PIANOFORTE CASE.

MESSRS. WRIGHT AND MANSFIELD, of 104, New Bond-street, have lately manufactured a grand pianoforte case for Sir Julian Goldsmid, Bart., M.P., a view of which was accorded to us last week, and as an example of inlaid woodwork, we may say we have seldom seen a more superb design. The top and sides of the instrument are of King wood, with a reticulation of tulip, stained, and other choice inlays. In addition to the rich borders, the top and sides have elongated medallions or panels with centre groupings of musical instruments in inlay. The legs are square, and are also richly relieved by inlaid woods of the same description, and the lines and general design are very satisfactory. In style the artist (we believe Mr. Lord) has adopted the Renaissance, or perhaps the geometrical diagonal network of marquetry, which be more correctly called Early Italian, freely treated. The instrument itself has been manufactured by the Messrs. Broadwood. We notice in other parts of Messrs. Wright and Mansfield's extensive show-rooms some very choice specimens of furniture in the Adams and Chipendale styles. One is a wardrobe, painted and highly polished, of a delicate cream or canary buff ground, with painted panels and medallions in the sides, and a large bevelled mirror in the centre compartment. The panelling is richly bordered with fluted margins, with gilt mouldings and enrichments picked out with a bright salmon colour. The panels are painted on copper. Over the mirror, the wardrobe is

finished with a scrolled pediment, while in the side compartments we observe an ingenious swivel hook for hanging the dresses, which revolves on a centre, a very obvious improvement on ordinary hooks. Among the choice examples of furniture in the Adams style, we noted a unique tripod table, designed and executed with considerable taste, thoroughly classic in feeling, and suggestive of the very elegant work of George II.'s time. The table and legs are of mahogany, painted to a cream-colour ground, and relieved by painted ornaments and gilt mounts. In the same style are to be seen one or two sideboards in which simple outline and refined ornamentation are observed; and the connoisseur of old furniture will be gratified by two finely inlaid specimens, one an Italian table, square in form, the top of which is divided into square panels by inlays, and another a choice secretaire of German workmanship. The table is certainly a very good example of the best Italian period. Those who are admirers of furniture of the more classic periods, and of marquetry and bone, will do well to visit the show-rooms of this firm, comprising as they do reproductions of art workmanship from the earlier Renaissance to the later style of Louis the Sixteenth.

Building Intelligence.

ARBROATH ABBEY.—For about a year past the town council of Arbroath, N.B., have been carrying out extensive improvements in the neighbourhood of the Abbey, partly with the object of better opening up the buildings to view, and partly to alter the Abbey-green, which adjoins the ruins and the churchyard, into a public garden or park. With this aim the Abbot's house and garden, which were private property, have been purchased, as have also a number of houses which intervene between the Abbot's house and the green. These it is intended to pull down, and two of these have already been demolished. The Abbot's house, which is inhabited, has been repaired, and the medieval vaults, including the great kitchen, which as well as part of the house is part of the old monastic buildings, have been put in order for the inspection of visitors. The Abbey-green has been levelled down with grass, and enclosed by a parapetted wall and railing, and it is intended by taking down a modern wall to connect it with the extensive garden of the Abbot's House. It is proposed to trench the garden adjoining the church, so as to lay bare the foundations of the monk's dormitory buildings, which are believed still to exist. The chapter house foundations and remaining walls have been cleared of soil, and in the process a number of stone coffins of ashlar, neatly jointed, were found, and have been carefully covered up again. A report of these operations having been communicated to H.M. Board of Works for Scotland, Mr. W. A. Robertson, of Edinburgh, the Surveyor of Works for Scotland, visited Arbroath last week, and inspected what was being done in company with the municipal authorities. The visit was for the purpose of protecting the rights of the Crown, to whom the ruins of the Abbey belong, and for whom the site of the chapter house is claimed. It is understood that Mr. Robertson expressed himself satisfied that the improvements in progress would be beneficial to the public, and it is expected the Town Council's scheme will be completely realised.

ARMAH.—A new Presbyterian Church has been opened at Armah. The style is Decorated Gothic. The exterior walls are built of square blocks of Armah marble, with dressings of Dungannon sandstone. The church consists of a nave and aisles, and accommodation has been provided for upwards of 830 persons. Galleries are placed against the walls on the three sides, and these are seated to hold 350 persons, while 480 can be accommodated on the ground floor. The nave consists of six bays, and is 50ft. in width, including the aisles, and 50ft. in height to the ridge. Octagonal turrets rise at each angle of the building, except at the corner of Russell-street, where a pinnaled tower rises 100ft. high to the belfry. Above this the spire terminates at a height of 185ft. in a lofty copper finial. The church will be heated by hot-water pipes supplied by Messrs. Mungrave and Co. The carving, of which there is a large quantity, has been done by Mr. Harry Hems, Exeter. Messrs. J. and J. Guiler, Bel-

fast, the builders, have executed the works from the designs of Messrs. Young and Mackenzie, Belfast, architects. The cost will be about £10,000.

CHARING.—The parish church of Charing, near Ashford, Kent, was reopened on Friday, the 23rd ult. The restoration, which has been under the direction of Mr. J. P. St. Aubyn, comprises the re-erecting of the nave and transepts, the removal of the western gallery, and the throwing open of the tower and western doorway, the stripping and relaying of the tiles on the roof of the nave and northern transept, the provision of a new roof and windows, and the restoration in flint work of the southern transept, which in 1812 was rebuilt in brick, and was not at all in character with the rest of the sacred edifice. The aisles have also been relaid with encaustic tiles. The large western window has been filled by Messrs. Clayton and Bell with stained glass, representing events in the lives of SS. Peter and Paul, to whom the church is dedicated. The cost has been about £2,400.

LEOMINSTER.—On Tuesday week the south nave of Leominster Priory Church was reopened after restoration by Mr. Edwards, of Leominster, under the direction of Messrs. Scott Brothers. The stonework has all been repointed, and a fine arched oak roof has been put in. An oak flooring has been put down, the passages being laid in with coloured tiles, and the eastern end of the nave is paved with encaustic tiles, supplied from Mr. Godwin's Encaustic Tile Works, at Lugwardine. The oak screen has been removed from the Norman nave and placed in the south nave, where service will in future be held. The screen has been filled in at the bottom between the columns with oak panelling, being divided into three panels, with small oak columns having moulded bases and capitals. A new stone pulpit has also been placed in the nave, supplied by Messrs. Jones and Willis. The partition which has for years past divided the south from the Norman nave has, of course, been removed, but on the other side the south nave is divided from the south aisle by a wooden partition some four or five feet in height, the contrast between the finished nave, and the desolate south aisle, with its uneven earthen floor, being very marked. The seating of the two restored naves consists of cathedral chairs, and both naves were used at the opening services. The organ remains in the Norman nave. The following figures will show the cost at present incurred in connection with the work. Restoring the Norman nave, £3,015; the south nave, £4,263; roofing south aisle, £693; restoring the fifth window from the porch in the south aisle, £473; extras, removing stalls and screens, about £100, thus bringing the total cost incurred so far in the work of restoration up to £8,543 10s. It is estimated that the sum of £12,000 more is required to complete the work of restoration, but this will include not only the interior, but the other portions. There still remains to be restored the four beautiful ball-flower windows in the south aisle, the south porch, the tower, and also the addition to the south nave of an apsidal chancel, the whole with fittings bringing the amount required up to the large sum of £20,000.

LOSTWITHIEL.—The ancient parish church of Lostwithiel was reopened on May 29th after restoration. The edifice, erected in the 13th or 14th century, belongs to the Transition period preceding the Decorated style. The spire, which was illustrated in the BUILDING NEWS two years since, is an object of much interest, spires being rare architectural features in Cornwall, or indeed, in the West of England at all. The lower part is Early English, consisting at the base of a square tower, over which is an octagonal lantern supporting the spire proper. The topmost part of this was not old, and was crippled. Under the immediate direction of the architect for the restoration, Mr. Joseph Clarke, F.S.A., of 13, Stratford-place, Oxford-street, W., this has been rectified. The old-fashioned boxes have been replaced with light modern pews. The old floor, consisting of irregular slates and stones, under which there was an accumulation of filth, has been replaced with a solid bedding of concrete, over which a wooden floor is laid, the aisles being paved with red encaustic tiles. Another great improvement has been effected by the removal of the gallery at the west end of the church, and placing the organ, which previously stood in the gallery, in the north-east corner of the church, near the chancel. The old lath-and-plaster ceiling has been removed, and a

pannelled pitch-pine roof with carved ribs and bosses over the chancel has been substituted. The carved work is by Mr. Harry Hems, of Exeter. The ceilings of the north and south aisles have been similarly treated. The walls have been scraped (the whitewash in some places was several inches in thickness) and plastered, and the stone facings and pillars have also been cleaned. The east-end of the church is lit by a large five-light tracery window, and there are several stained windows in the aisles, the remainder being of cathedral glass. Two small windows have been cut in the west-end of the church in order to relieve the heaviness of the wall caused by the removal of the gallery. The belfry, which was previously entered by a narrow door, is now thrown open to the church. The contractors for the restoration were Messrs. Brown and Phelps, builders, of Lostwithiel.

MANCHESTER.—The new wholesale fish-market at Manchester was opened on Thursday week. The elevation of the market frontage to High-street has been carried out in uniformity with that portion of it which was built about seven years ago. The style is Free Gothic of a Continental type. The newly-built part of the market has four entrances, two of which are for vehicles only; the gateways are of large proportions, filled in with handsome wrought-iron gates, which are probably the largest in the provinces erected for such a purpose. The whole of the wrought metal-work has been executed by the Coventry Art Metal Company. At each angle of the building an oriel window has been introduced, with granite shafts to the jambs, the angles taking a circular form from above the oriels, and at each end the roof is turreted in pavilion form. The architects are Messrs. Mangnall and Littlewoods, of Manchester, and the builders Messrs. Robert Neill and Sons.

MOSSLEY, NEAR MANCHESTER.—The foundation-stone of the new parish church of St. George, Mossley, was laid on Saturday last. This building is being erected on a site adjoining that of the old church, and is in the Late Decorated style. It consists of nave and aisles, 71ft. by 61ft. On the north side of the chancel is the tower, 18ft. square, and 90ft. high, which will contain the organ and an entrance porch. On the south side is the vestry, with heating chamber below; a projecting narthex is formed at the west end by two porches and the staircase to west gallery. The church will seat 1,010 persons, including 230 children in west gallery. The materials are local rubble, faced with outside Yorkshire parpoints and Alderley dressed stone, and the walls will be plastered inside. Pitch-pine will be used for seats, screens, and other fittings. The cost of the whole, when completed, will be about £6,550, including all expenses. The work is being carried out by Mr. Edward Marland, of Mossley, from the designs and under the superintendence of Mr. A. H. Davies-Colley, architect, Manchester.

PECKHAM.—The church of St. Jude, Peckham, was consecrated on Whitsun Eve. The church accommodates 800, and cost £5,300. The architect is Mr. Blomfield; the style is Early English, and consists of nave, aisles, transept, chancel, and vestry. It is built of stock brickwork, with red bands and arches. The chancel has been recently decorated by Messrs. Heaton, Butler, and Bayne. The white marble font has been executed by Mr. Earp.

RINGWOOD.—A reredos in memory of the late vicar, the Rev. George Williams, has been erected in the parish church of Ringwood, Hants, during the past week. It extends the whole length of the altar, rising to a height of 6ft. 10in. It consists of three panels of Derbyshire alabaster, standing on a slab of Sicilian marble. From this marble slab, which forms a retable, rise four clustered bases supporting twelve columns of Devonshire marble, surmounted by foliage caps of Early English character, from which spring the arches of the triplet of gables, which are richly crocketed. The columns are carried up to form pedestals for four angels, carved in white alabaster, and holding quarterfoil shields bearing the emblems of our Lord's Passion. Each panel is lined with a mosaic in gold, by Messrs. Simpson and Son, of London, that in the centre being filled by the Agnus Dei and the other two with the Alpha and Omega. The designer and sculptor was Mr. G. W. Searle, of Brixton. On the south side of the chancel, the fourth lancet-light from

the east end has been filled with stained glass as a memorial to a deceased parishioner. The subject is the "Raising of Lazarus," and the artists are Messrs. Ward and Hughes, of London, who have previously executed other work of similar character in the chancel of this church.

SPARKBROOK.—A new Baptist chapel at Sparkbrook was opened on Whit Tuesday. The style is a modern adaptation of the Early Geometrical style, the materials used being fine red bricks with Bath stone tracery, pinnacles, and copings, the constructive arches and other decorative features being worked out with moulded and ornamental bricks and terra-cotta. The body of the chapel is in the form of a parallelogram, 69ft. long by 40ft. wide, the central nave being divided from the two side aisles by four cast-iron ornamental columns on each side, which support an arched of framed woodwork and the arched timbering carrying an open roof, 46ft. high from the floor to the apex. There are galleries on each side, and a large gallery is carried over the main entrance. The chapel will accommodate altogether 1,120 persons. The building has been erected from the designs of Mr. Hale, architect. Messrs. Davies Brothers were the builders; the iron columns and gasfittings were the work of Messrs. Hart, Son, Peard and Co. The total cost of the chapel is about £7,300.

TIVERTON.—A memorial pulpit has just been erected at St. George's Church, Tiverton. The building is Classical, and the pulpit, designed in the Jacobean style of the early 17th century, harmonises well with its surroundings. It is of wainscot oak, and on plan is hexagonal, each angle being sustained by richly-wrought brackets. The five canopies contain recessed niches, in which stand sculptured figures in bold relief, representing SS. Matthew, Mark, Luke, John, and Paul. The respective emblems of these Saints are also carved. The pulpit is approached by convenient stairs, having massive handrails and worked balustrades. The whole has been designed and carried out under the immediate superintendence of Mr. Edward Ashworth, architect, of Exeter. The carved figures and symbols are by Mr. Harry Heins, of the same city.

THE ELEPHANT AND CASTLE THEATRE, NEWINGTON, S.E., was opened on Saturday night, having been rebuilt after destruction by fire. It is now considerably higher, the accommodation is larger, and the facilities for egress have been greatly improved. The length from back to front, including stage, is 106ft., the stage being 40ft. at the deepest part; the width of the proscenium is 30ft., and the entire width of the house is 67ft. There are four rows of stalls, having two exits, and a pit seating nearly a thousand persons, and surrounded by a promenade with three exits—one 7ft., and the other two each 5½ft. wide. A new feature is a saloon over 50ft. long, on the left-hand side of the pit looking towards the stage; this saloon is built underneath one of the platforms of the Elephant and Castle Railway-station. The dress-circle is approached from the main entrance by a staircase 7ft. 6in. wide, and attached is another saloon. Over this is a spacious amphitheatre and gallery. There are also ten boxes. The dressing-rooms for actors and actresses are in a building separate from the theatre. The internal decorations have been executed by Messrs. Pashley, Newton, and Young, from designs furnished by the architect, Mr. Frank Matcham, of Bedford-row. The principal colour used is a pale green, the front of the dress-circle being panelled out in amber satin. The ceiling is a circular dome, and the top portion of the proscenium is curved towards the auditorium with the aim of increasing the acoustic properties of the building. The lighting is effected by a sun-light containing 206 burners, supplied by Messrs. Z. D. Berry and Son, of Buckingham Palace-road. The builders are Messrs. Brass, of Chelsea.

The new poorhouse and asylum which have been erected at Smithton by the Greenock Parochial Board were opened last week. The buildings, although estimated at first to cost £45,000, have already had expended on them about £100,000. The style adopted, according to a plan by Mr. Starforth, architect, Edinburgh, is Scottish Baronial.

A new Christadelphian synagogue was opened in Lion-street, Abergavenny, on Whit-Sunday. It has been erected at a cost of £200, and seats 130 persons. Mr. John Thomas was the contractor.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the ENGLISH MECHANIC AND WORLD OF SCIENCE, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Twopenny, of all booksellers and news-vendors. Post free 2½d. Office: 31, Tavistock street, Covent-garden W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33s. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—J. W. L.—J. F. M.—M. and Co.—F. and Co.—W. W.—J. D.—W. S. B.—S. E. Co.—A. W. K.—F. R.—F. W. B.—P. and A.

DRAWINGS RECEIVED.—R. N. S., T. G. J., T. E. C., O. W. and Son.

C. O., Leicester. (People who know little about their business are generally willing to work for nothing, and people who employ them deserve all the gratification they are likely to derive.)—PERPLEXED. (You cannot "register" a "patent." Send to one of the patent agents whose advertisements appear in the *English Mechanic* for a copy of their instructions to inventors.)

"BUILDING NEWS" DESIGNING CLUB.

DRAWINGS RECEIVED.—C. W. D., North West, X. L., Operam Dare, Factable, Colorado Beetle, Be to Its Merits, &c., Ivanhoe, Peter, Che Sara Sara, Melnotte, Sub Silentio, Ieh Dien, "Maggie, alias Such a Dog," Motto J., East Anglian, Nitor, S. in Circle, Ognore, Burswell, Try, Bog, Cleo, Elvée, Honey Dew.

LIST OF SUBJECTS.—1. A row of six labourers' cottages, three having two and the remainder three bedrooms each. A wash and bakehouse to be arranged in the rear. The plans to show all conveniences. Plans, elevation, and sketch. Scale 5ft. to the inch. 2. A garden seat to accommodate six persons. Inch scale, section and sketch. Material, iron or wood.

Correspondence.

RAMSGATE PROPOSED NEW ROAD COMPETITION.

To the Editor of the BUILDING NEWS.

SIR,—My attention has been called to a statement under the above heading in your last week's journal, in which your correspondent's information is so utterly at variance with the facts that I am sure you will allow me space to state that neither directly nor indirectly have I engaged in the above competition.

I am totally ignorant of the author of the design imputed to me, and I cannot but feel that a great injustice is done to a competitor whose name I am entirely ignorant of.

Not knowing any of the competitors, I cannot but conclude that some disappointed local celebrity is referred to by your correspondent as canvassing the town, which I hope is as devoid of truth as the previous assertion, for, of one

thing I am sure, all canvassers have kept clear of your obedient servant,

ALFRED R. PITE,
One of the Ramsgate Commissioners.
44, Bloomsbury-square, W.C.,
3rd June, 1879.

TALL FLAGSTAFF.

SIR,—Among the items in your issue of the 30th ult. designated "Clips" is the following:—"A new flagstaff, erected last week on the tower of Shelton Church, Staffordshire, deserves notice on account of its being, it is said, the largest in England. The pole is the trunk of a Russian larch 65ft. high, &c."

This may possibly be the longest flagstaff on a church tower; otherwise the dimension is not great. A flagstaff has just been erected in Sefton Park, near this town, 123ft. high, all one pole, being nearly as long again as the one at Shelton.—I am, &c., J. SIRETT BROWN.
58, Chatham-street, Liverpool, May 31st, 1879.

Intercommunication.

QUESTIONS.

[5786].—**Edington Church.**—In your last number (p. 618), it is stated that "the parish church of St. George, Edington, has been entirely rebuilt." I beg to inquire if the building destroyed was the very interesting church erected by Bishop Edington, the predecessor at Winchester, of William of Wykeham. It appears to me that it is so, and hence a valuable stepping-stone in the history of English architecture is lost for ever.—W. P.

[5787].—**Strains in Collar-Beam Roof.**—Will one of your kind correspondents show, by means of a diagram, the strains which come upon a rafter, the collar, and the supporting walls of an ordinary span roof, having its collars fixed so that one-third of the length of the rafter is below them; no tie-beams nor purlins.—S.

[5788].—**Ormolu.**—Can I be referred to any work which explains the original manufacture of this material? All the modern imitations rust or become black in a short time, because lacquered. I have been informed that the old work was plated with gold, or, at least, was well gilt, and hence it keeps clean and bright.—W. P.

[5789].—**Licences and Stamps.**—Is it necessary for an architect-surveyor who is occasionally employed to estimate the value of dilapidations as between the parties concerned, also to measure up and value work done by builders on measure and value also to value house and land for mortgages, to take out a licence? And secondly, does the account of measure and value or report on dilapidations made to the parties require an appraisal stamp?—W. V.

[5790].—**Quantity Surveying.**—Will some correspondent please give the average time in taking off, abstracting, and bringing into rough draft bill of quantities for an average brick job, with stone dressings, for about a £5,000 contract—in hours preferred?—G. W.

[5791].—**Water Exuding from Verandah.**—I should be much obliged if some scientific man would explain the following:—I built a verandah to a house near the seaside about a year ago, and now every day when the sun shines water drops from every exit in the boarding underneath and at the eaves. It is plain tiled and boarded on top of the rafters with wellings, shutes, &c. There are two gables. It does not drop except when the sun is hot or even during rain. The weather has been alternately wet and fine every few days, and warm.—R. G. P.

[5792].—**Manufacturers' Catalogues.**—Will any of the readers of the BUILDING NEWS kindly inform me as to the best method of keeping manufacturers' catalogues so as to be of easy reference in the office? One difficulty I find is the different sizes, another is the variety of forms; some are bound, some half bound, some in pamphlet form, and some simply sheets. Any suggestions on the subject will oblige.—INQUIRER.

[5793].—**Fountain Basin.**—I shall be obliged to any one who will give me information as to the best way of jointing and forming bottom to a marble basin for fountain, size 6ft. 6in. over all, with base in centre for fountain, 2ft. 6in. diameter, water-line to be 6ft. above floor line, and depth of water about 15in. I am aware it would be well to have it cut out of a solid piece, but as it would require a block of about 105ft. cube, the cost would be too great. A section from some of your readers would be of service.—SERIA.

REPLIES.

[5772].—**Red and White Wood.**—In reply to "Kippax," red, or otherwise called yellow deal, can be distinguished from white deal by a variety of ways, which are the result of the component constituents of each being in some respects quite different. Red or yellow deal is a resinous wood, giving it the quality which so effectually resists the action of damp, and renders it useful for external work exposed to the weather, being *Pinus sylvestris*, growing in districts of suitable soil and climate, frequently on sandy soil, and when cut it is somewhat close grained, especially on the end, and in no wise harsh in appearance nor touch, its knots are but very seldom loose, and are of a rich reddish colour, and as the timber seasons the knots will not much project beyond the wood. The end of a new yellow deal is smooth and reddish, and may thereby be known from the end of a white one without any close inspection. The annular rings on the grain when cut endwise do not prominently appear, because the intervening spongy pith contains so much resin as to prevent its crumbling away from the rings or shrinking away

from them, and the same characteristics hold good with respect to the grain cut lengthwise, the intervening spongy pith and the annular rings adhering closely to each other by means of the resin, and in consequence it does not split so very easily, and it is also softer than white deal, and its scent is not strongly perceptible. When sawn or planed it has a dullish look, and is almost entirely deficient in reflective brilliancy, and there will not be turpentine discoverable in or on it; but with respect to colour, its annular rings are usually strongly marked by being of a darkish orange colour, but otherwise the wood itself is sometimes of a very light yellow, which might be well depicted by a light wash of raw sienna, with perhaps burnt sienna or umber for annular rings. Its medullary rays are hardly discernible, and consequently it has no noticeable silver grain or figure. Memel timber is of the foregoing kind, and *Pinus sylvestris* also comprises Riga fir, Danzig fir, and Onega, Yellow Archangel, Wyburg, Gefle, &c., and it is the Scotch fir of Britain. The Onega is very hard, tough, and durable, and good for warehouse floors. Danzig is knotty and tough, Riga is the largest timber, Memel the strongest red deal. *Pinus sylvestris* grows farther north than any tree but the dwarf birch. The pale yellow Swedish *Pinus sylvestris* is very cheap and inferior. The best red deal should be strongly marked, red and heavy. *Pinus abies* or *Abies excelsa*, or commonly called Norway spruce, is that which is otherwise called white deal, and there are many varieties of it, some of that growing in America being black, some red, and some hemlock spruce. The kinds in use in this country are mostly Christiana white, Petersburg white, and Riga white. Christiana is usually preferred, but the best of the other kinds are excellent. There are four different qualities of each kind recognised. White deals, if uncut, may be known at once by observing the grain at the ends. If the ends have a rough sort of appearance and of an almost indescribable colour, and the annular rings stand out in appearance as sharp and thin as the back of a knife, and with the intervening pith wood between rings sunken and crumbled and gone to some extent, then no doubt need to be entertained but what it is spruce; and looking at it flatwise it will be of smoothlike glossiness in places, even though it is rough from the saw, and is harsh and slippery to the sense of touch. Its knots are generally darkish and frequently loose, and, like their wood, are excessively harsh in appearance, and the wood shrinks from the knots and leaves them standing up in relief on the surface. The spruce also contains much turpentine, which may be seen at times running in streams over the boards if exposed newly cut to the weather. When planed it has a silky shining appearance, and if it were not so common because cheap it would be considered a beautiful wood when polished, that is, if perfectly seasoned and coated to prevent the grain from rising. If exposed to the atmosphere and to water, the annular rings will, on the flat way of the grain, rise, or the other wood will wear away from between and leave them standing up as so many sharp ridges. Spruce is unfit for work exposed to the weather, and it smells of turpentine strongly. There are yet other kinds of pine used in this country, and to be sure of knowing one kind one should know all. There is the *Pinus strobus*, or American white pine, and which is one of the kinds usually called pine by practical builders and timber merchants. We call it yellow pine, and it differs from the *Pinus abies* principally by the entire absence of tendency of the annular rings to project beyond the wood, either on the end or on the face, and in the medullary rays being more discernible; and in some kinds at the least, if the timber be cut with a medullary ray on its face the wood will then show small silver grain or figure, somewhat similar to silver grain in sycamore, in maple, in beech, and in Spanish mahogany, &c., and which, by the bye, is the criterion whereby Spanish mahogany may be told from a good sample of Honduras or Cuba mahogany. The *Pinus strobus* is white in colour American. There is also the *Pinus mitis* and the *Pinus palustris*, each being American yellow pine (we call them red), and not dissimilar, except in colour, to the *Pinus strobus*. They are heavier than the *Pinus strobus*, and very strong and elastic. Then there is the Canadian *Pinus resinosa*, or pitch pine, being a heavy strong red pine, but having the annular rings as with the other pines not projecting. It is of considerable size. It is much heavier than any Baltic timber. It is worthy of notice that the heaviest American red pine does not equal in weight, average for average, the lightest Baltic red deal. Now the American pines, except the pitch pine, have very much turpentine in them, and from the red *Pinus palustris* the Americans get the most of their tar and turpentine. In conclusion, it may be remarked that yellow deal, especially when wet, may be known by its dark bluish indigo colour sap wood, the sap in the white deal being hardly discernible. The Memel is the strongest of the red deals, but the Norway spruce is immensely superior in tensile strength, and the best red American pine is stronger than Baltic red deal. Norway spars are used for ladders. Pitch pine is not so strong in tension as Norway spruce, but in compression it is immensely strong, and which in a beam will raise high the neutral axis; and consequently a pitch pine beam is almost as strong as English or Canadian oak, and much stronger than Danzig or Adriatic oak. Norway spruce is very tough and elastic, and red pine is even much more elastic. —HENRY AMBROSE.

[5772].—Red and White Wood.—This question has been answered before in the BUILDING NEWS. Red wood, as that of the Northern pine (*Pinus sylvestris*), is of a reddish yellow, but of such different degrees of brightness that as far as this quality alone goes it may be mistaken. The annular rings are narrow, of a reddish colour. White fir or spruce is of a yellowish-white colour, the rings are well defined and the surface is glossy in parts. It is more knotty, and the sapwood is not easily distinguished. But no description can adequately make the difference between the two thoroughly understood. —G. H. G.

[5773].—Lime.—On p. 619, H. Ambrose says:—"Poor limes contain no alumina, but insoluble silica." I think the writer has made a mistake, for "poor" or "meagre" lime is the term generally used for hydraulic lime, which name it obtains from its inability to increase much in bulk when slaking. Therefore if poor lime is hydraulic lime it must contain both silica and alumina, that is common clay combined in certain proportions. —J. S. GOLDTHORP.

[5774].—Thrust of Arches.—First with respect to the piers: these must have a foundation such as will most

certainly safely sustain the 50 tons; but I doubt whether with heavy wet snow and such a violent storm of wind as on March 2nd, 1878, pressing on the roof, and with the possibility of the upper floors being utilised in perhaps one or two adjoining houses as depositories for part of the stock or appliances used in the business carried on, as, for instance, say, the enormously heavy type racks of a printer stood as near to the light as he could get them, or perhaps a stationer, with his heavy reams of paper, &c. In such a case it might be easy to have 100 tons on a pier, and which, according to rule, should be capable to support 10 times its safe load, and the 100 tons, or, say no more than 50 tons, would give us 500 to 1,000 tons as a crushing load. Now stock bricks in lias lime are reputed to fail with 17 tons on a foot superficial, and to entirely crush with 27 tons on a foot when only a foot high, but 12ft. high would render them much weaker still, as in that case they would not wait till they were being crushed, but would vertically crack, and bulge bodily out from the party walls, and let all down depending on them. Therefore we revert to one-tenth of the crushing weight as the safe load; and it is considered that under such conditions the height may be ten times the diameter or thickness of pier, and therefore two tons per foot super will be the utmost we can safely calculate on, and we have 3ft. super on our pier of 2ft. by 1ft. 6in., which will safely carry, say, 6 tons, and no more. Gault bricks and real Portland cement, and the utmost precaution being taken to have the strongest cement, which one must see to himself and know how to test it, and the men being watched during every minute of the time the piers are being built, otherwise they might use mortar in the place of cement if the cement ran short, just for a few courses, or mix sand with the cement, under the erroneous idea that sand will strengthen the cement. Sand strengthens, in due proportion, lias lime, but weakens cement. Then with gault bricks and the best Portland cement such a pier would support (if its foundation would) from 12 to 18 tons, but we have from 50 to 100 to support; and therefore there are but two convenient practical ways: the one, to build into the party wall a properly cast iron stanchion of sufficient area to support the number of tons at so many times its diameter. If more than six times its least diameter it begins to diminish in strength, and at twelve times would require more metal to retain the same strength. Rule for iron columns and standards thus:—Columns and standards of similar ratios of length to diameter, and having similar sections in proportion the one to the other, are to one another in strength as the direct ratio of the squares of their lengths, and from which, if time would allow, we could deduce formulæ and examples, but we may say that above 45in. in sectional area of a column or standard would properly support the weight in question if on a proper foundation and properly fixed with felt or lead or pine or other means to prevent fracture, and the soundness and excellency of the material being guaranteed by a trustworthy founder, and the verticality of its axis tested while they are fixing it, as it will not do to trust to instructions alone without seeing that they are carried out fully. Hard stone ashlar would be the other method. With respect to the abutments for arches, an arch of 18ft. span and 1ft. versed sine would exert a thrust thus: If half the span (in our case 18 ft.) divided by 2 feet be made radius, then as its radius is to its tangent—that is, supposing it is sufficiently loaded, and as our radius is 9 and the degrees give tangent equal 1ft., then we shall have 9 times the thrust on abutment that we have weight at crown of arch, and if we have, say, 100 tons on the pier, then take 50 as bearing on the crown of arch—i.e., as a load equally distributed and 9 times 50 = 450 tons to resist, or, if we say 50 tons on the pier then 225 tons on the abutment will be the thrust. As we can safely give 5 tons strain in tension on 1in. square of wrought iron we should require from 45 to 90 square inches of wrought-iron ties to hold in our end abutments, but such would be preposterous and the most unskillful way of going to work, because our arch, if it would in itself bear its pressure, would do nothing to counteract its effect on the tie-rods underneath it. The proper way to go to work would be the usual way—viz., to put a proper riveted girder where the web and stiffeners will counteract the tensile strain by the adhesion of the flange in compression where one cannot break until the other does, and which would effect a great saving in metal. And, again, if an arch were adopted it should not rise less than 1in. to 1ft., which would give 2ft. 3in. rise, but an arch with much work to do should rise 1/3 of its span, which would give 6ft. rise; and again, there is a place for everything, and an arch of long span over a shop front I should think must look very unattractive, and tend to depress the height of the top ash and exclude light, and to render high the window sills above. —HENRY AMBROSE.

[5782].—Right of Access.—In reply to "X. Y.," it may perhaps be considered that in the first place, supposing the steps to be fixed by any of the following methods—viz., by digging into the ground for the purpose of receiving a foundation or supporter to steps, or if the steps have been cemented to the original building, or some positive part thereof, by mortar, or united by nails or otherwise, to some erection previously attached to the ground, then if the steps have been or are fixed by any of the above methods the tenant or lessee cannot remove them without permission of his landlord, and which he should obtain in writing, and if the tenant should remove them then he would be liable to an action for dilapidations; but if the lessee fixed same with lessor's permission, given and obtained with the view to their being used for the purpose of the lessee's trade or calling, in this case the lessee would possess the privilege to remove them at any time previous to his giving up possession of the premises; and in the latter case the lessee can also remove them at any time during his tenancy and erect something else in their place, but in any of the preceding cases he will be required to make good any injury or damage his fixtures may have caused before the termination of his occupancy, but the preceding has supposed that the lessee carries on a trade or business on the premises; but if he does not, then he can remove nothing without permission by the landlord, and as a general rule the tenant can remove nothing whatever that is affixed to the freehold or any part of the same, and which is therefore a constituent part thereof, and cannot be removed by the tenant without leave of the landlord or reversioner, and that which he is privileged to fix and remove must not be fixed with nails nor let into the ground without permission, and permission for its removal should likewise be obtained before using same. If

the ground the steps stand on was not included in the tenement as an easement, either by being specially mentioned or else by having for 20 years been included in the same tenement or freehold, then the lessee would have been trespassing by placing the steps there if the ground belongs to the lessor as private property unless the lessor gave his permission for the steps to be placed there, and if so, and no time was mentioned, then it would evidently be during his pleasure; he having the privilege of access to the ground, could of course claim same at any time, because an agreement cannot legally be broken and still hold good, and for a lessor to let premises in lieu of a consideration of so much a year; that agreement cannot be altered without being broken and a new and supplementary one entered into in its stead, and it is manifest that a new agreement could leave no cause of dispute involving the old one, and therefore whether the lessee did or did not have permission to put steps on his landlord's ground, if he moves then he can have no right to the ground because his steps had stood on same, but only if the landlord had specially let him that piece of ground for a consideration. And, lastly, the lessee cannot claim the ground after a lapse of time which he cannot make good his claim to at the present time unless the landlord should have entered into a contract with the would-be lessee that he would let it to him so that his occupancy should commence at a certain date, and in this last case, if the landlord failed to keep his contract then the would-be lessee would have a remedy by action for damages sustained by him through the breach and non-fulfilment of the contract to let entered into by the landlord. —HENRY AMBROSE.

[5784].—Discharge of Water.—There are two formulæ in general use for calculating the discharge of pipes running full, the Dutch and the Irish. The former, known as Eytelwein's, is not so correct under varying circumstances as the latter, known as Neville's.

g = Supply in gallons per minute.

d = Diameter in inches.

r = Hydraulic mean depth in feet, that is the quotient of section by perimeter.

s = Sine of inclination or quotient of head by length.

$g = 2.04 d^2 \left[140 \sqrt{rs} - 11 \frac{3}{4} \sqrt{rs} \right]$ Neville's formula.

$g = 28 \sqrt{d^5 s}$ Eytelwein's formula.

It is preferred to calculate the discharge in feet per minute; recollect that a cubic foot contains 6.24 gallons. In the case in question—

g is unknown

$d = 20$

$r = 9/12$

$s = 3/36$

The rest is obvious.—OLD WATERWORKS.

LEGAL INTELLIGENCE.

ARCHITECTS' COMMISSION.—Ingram and Holland v. Mark Cockle.—This action was tried in the Court of Common Pleas on Monday and Tuesday week, the 26th and 27th May, before Lord Denman and a common jury. It appeared that in the early part of 1878, the defendant purchased the Centurion public-house in the Broadway, Deptford, of a Mr. Cole, who had at that time engaged the plaintiffs to negotiate an extension of the lease of the house from the Bridge House Estates Committee of the City Corporation, and, if successful, they were to be employed as architects in the re-erection of the house at the usual commission of 5 per cent. The defendant appeared to have taken a transfer of this arrangement as part of his bargain, or as he expressed it, he was "to stand in Cole's shoes." Subsequently the new lease was obtained, and plans were prepared for building the new house; but, according to the defendant's case, plaintiffs delayed the completion of the plans until the winter season prevented the erection of the house in that year. They moreover, against, as it was maintained, the wish of the defendant, insisted on taking out the quantities of the new building and sought to introduce a builder of their own nomination instead of a local builder who was preferred by Cockle, and these disputes ended in an angry interview on the 7th of October last, when the plaintiffs intimated to the defendant that as he seemed so much dissatisfied he had better pay their fees and go to some other surveyor. This advice the defendant took so far as to instruct Mr. W. T. Hunt, of New Cross-road, to prepare fresh plans and specifications of the proposed work (which is now being carried out by Mr. Hunt) and to tender to the plaintiffs a nominal sum as compensation for the services rendered. This was refused by them, and the action was brought to recover £200 as commission at the rate of 5 per cent. on the estimated cost of the new building, and £80, or 2 per cent. for taking out the quantities, in all £280. The evidence was of a conflicting nature as to the original agreements between the parties and as to the interview on the 7th October, when the arrangement came to an end, and as to whether the plaintiffs discharged themselves or were discharged by the defendant, also in either case as to the amount they would be entitled to under the peculiar circumstances, the plaintiffs having retained the whole of their drawings and specifications. Mr. Hunt was called to prove that he had prepared entirely fresh drawings, irrespective of those of the plaintiffs, and that he had had no assistance from them nor any advantage from the work which they had performed. The defendant's counsel contended that this being the case, and the plaintiffs by their dilatoriness having caused the defendant great loss through the delay in proceeding with the erection of the new house, and having, as he contended, discharged themselves, they were only entitled to recover a nominal sum, or, at any

rate, no more than the sum paid into Court, £50. After hearing the evidence, which occupied two days, and the very clear summing up of the judge, the jury awarded the sum of £160, being £100 for the preparation of plans, &c., and £60 for the quantities.

Our Office Table.

THE annual meeting of the Sanitary Institute of Great Britain was held on Thursday week, at the rooms of the Society of Arts. Dr. B. W. Richardson was in the chair. The report showed that four examinations have been held, under the direction of the Council, for local surveyors and inspectors of nuisances. Twenty-six candidates had presented themselves, of whom 12 wished to obtain certificates of competence as local surveyors, and 14 certificates as inspectors of nuisances. Five surveyors and 13 inspectors of nuisances had gained certificates, and seven surveyors and one inspector of nuisances had failed to satisfy the examiners. Sixteen candidates had expressed an intention to present themselves for the next examination in June. A discussion arose on a resolution, which Sir Antonio Brady had given notice he should propose, to alter the first by-law, so as to make women admissible as associates, members, and fellows of the Institute. Sir Antonio Brady was not present, and though his resolution was supported by several gentlemen, including Dr. Richardson, it was rejected on a show of hands. On the motion of Dr. Lory Marsh, who was supported by Dr. Russell, of Edinburgh, and Captain Douglas Galton, a resolution was carried suggesting that the Council should proceed with as little delay as possible to carry out that part of the basis of constitution which related to the establishment of a school and classes for the technical teaching of sanitary science.

MR. JAMES HODGES, C.E., the contracting engineer and agent, under the late Mr. Robert Stephenson, of the famous Great Victoria Bridge over the river St. Lawrence, at Montreal, which was opened by the Prince of Wales on the 25th of August, 1860, died at his residence at Perry-hill, Bagshot, on the 28th ult. Mr. Hodges, who was in his sixty-sixth year, was born at Queenborough, Kent, and from 1839 till 1841 was assistant-engineer to the late Sir William Cubitt, at Dover, where he had charge of the tunnels and cliff works of the South-Eastern Railway and of the great blast of the Rounddown Cliff. From 1841 to 1843 he was resident engineer, in Norfolk, for the railway works under Messrs. Robert Stephenson and George Parker Bidder, and constructed the new harbour at Lowestoft. He proceeded to Canada in 1859, as engineer for Messrs. Peto, Brassey and Betts, and constructed several hundred miles of the Grand Trunk Railway, including the celebrated bridge above mentioned. This great work, which connects Canada with the seaboard States of North America, is two English miles long, less about 60 yards, or about seven and a half times longer than Waterloo-bridge. It is supported on twenty-four massive piers, and is 60ft. above the summer level of the river, the cost of erection being £1,700,000.

We have received from Mr. John Hogg, of Paternoster-row, a selection of Mr. F. Soenneken's productions for facilitating writing, which are worth notice. A text-book of "Round Writing"—a system of calligraphy which its inventor particularly recommends to architects and others, some pens specially adapted to execute the same, which seem well suited to their purpose; some other pens for rapid writing, about which we can speak with more confidence, being among the best we have ever tried; a pen-holder made on a new principle for use therewith, which though very light, strikes us as being too thick, and a "writing and drawing instrument" which is quite a curiosity in its way, by means of which the nine pens sold with it, 144 different double, and 504 different triple lines may be executed. Very little practice would we should think render this last named instrument a most useful one in the hands of a draughtsman or ornamental writer.

At the meeting of the Metropolitan Board of Works on Friday, the election of district surveyor for Putney and Roehampton, in place of the late Mr. Horace Field, took place. The candi-

dates were twenty-six in number, but one, H. H. Bridgeman, was struck out of the list of those to be voted upon, on account of non-appearance at the precise time of election. The candidates were first reduced to six by a single vote, and then a series of votes were taken, the lowest on the poll being successively struck off. The following was the order of voting, the names of the candidate struck off at each voting being indicated by an asterisk. Preliminary vote: J. B. Badcock, 4; C. W. Brooks, 11; R. H. Burden, 6; E. Carritt, 17; A. Conder, 13; J. S. Edmeston, 14; J. M. Ferguson, 9; F. Hammond, 21; E. R. Hewitt, 0; J. W. James, 20; W. A. Large, 14; H. Lovegrove, 14; F. C. Notley, 14; Alex. Payne, 27; J. S. Quilter, 5; W. Smallpiece, 7; T. Stone, 6; E. Street, 22; W. Tasker, 23; F. Todd, 10; J. Goldicott Turner, 10; T. Williams, 17; T. W. Willis, 27; and J. Young, 14. 2nd vote: Hammond,* 16; James, 17; Payne, 22; Street, 17; Tasker, 19; Willis, 26. 3rd vote: James,* 11; Payne, 21; Street, 17; Tasker, 19; Willis, 26. 4th vote: Payne, 22; Street,* 10; Tasker, 18; Willis, 25. 5th vote: Payne, 23; Tasker,* 16; Willis, 24. Final vote: Payne, 17; Willis, 26. Mr. Willis has, therefore, been elected. It was agreed to advance the following loans to local authorities in the metropolis: Holborn District Board, £16,000, for re-creation of new offices; Hackney District Board, £10,000, for paving works; Vestry of St. George the Martyr, Southwark, £6,500, to defray cost of paving works; Chelsea Vestry, £1,400, to defray cost of erecting public offices and mortuary at Kensal-road; St. Marylebone Guardians, £40,000, towards cost of infirmary in course of erection at Notting-hill; Holborn Guardians, £25,000, for building of infirmary at Highgate; and Rotherhithe Commissioners of Baths and Washhouses £1,500, for purchasing leasehold interest in ground on which it is proposed to erect baths and washhouses. Mr. Robert Taylor brought forward the disastrous floods which were occasioned on the previous day in Lambeth and Southwark, which he attributed to the unexpected rainfall and to the defective sewerage of the South of London, and the whole question was referred to the Works Committee for consideration and report.

MR. HENRY LEIGHTON, of the Grange, Lambton Park, has died, at the age of 63 years. The deceased gentleman commenced his career at Ravensworth Castle, where he was engaged eight years. Having removed to Newcastle, he was employed on several important public works, including St. Mary's Catholic Cathedral for two years, and for some time he was at Carpen, Lancashire. Returning to Newcastle, he acted as inspector of the Church of St. Mary, Rye Hill, and on the completion of that edifice he entered the offices of the late John Dobson, architect, who placed the Hexham Town Hall, also the Hayhole Dock, with several other important works under his care. Mr. Dobson ultimately placed him as manager and inspector of the building of Lambton Castle, and after the death of Mr. Dobson Sir Sidney Smirke, R.A., retained him as his inspector. Mr. Leighton also held the situation of architect to the estates of the Earl of Durham, and inspected the progress of the building of Fenton House, near Wooler, the Northumberland residence of the Earl of Durham.

SOME time since the Vestry of Paddington came to the sensible resolution to abolish the contract system as regards dusting, slopping, and watering, and to do the work themselves. For this purpose they purchased wharves, horses, and plant, but have since found that they had not secured any place in which to deposit the breeze until it is purchased by brickmakers. The subject was referred to the general purposes committee of the Vestry, who reported on Tuesday, recommending the purchase of a piece of land at Alperston on the banks of the Grand Junction Canal, the price not to exceed £3,200. In moving the adoption of this report, Mr. Flood asserted that there exists a combination of contractors to endeavour to prevent the vestry selling the breeze to the brickmakers, and said that it was essentially necessary that the vestry should purchase the land, so as to be put in a position to compete with the contractors. A discussion of some hours' duration ensued, the opposition contending that it would be far better to sell the breeze to the contractors, but eventually the motion was carried by 31 to 19 votes, and the vestry will therefore apply to the Metropolitan Board of Works for a loan of the sum required.

It is proposed to hold an ecclesiastical art exhibition in London during May and June, 1880. It will be open to British and foreign art. The first division will comprise a loan collection of Medieval and modern ecclesiastical art; the second division will be reserved for architects, artists, and others who exhibit original work; and in the third division will be exhibited works of manufacturers. Amongst the principal classes will be pictures for churches (schools various); cartoons for wall paintings, mosaics; architectural drawings; cartoons for stained glass; mosaics; sculpture; illuminations; stained glass; wood and ivory carving; bells; embroidery, tapestry, and textile fabrics; missals; heraldry and sacred symbolism; metal work; tiles; models of churches (ancient and modern); and what is classified under the head of funeral reform, Christian and sanitary. The Secretary, *pro tem.*, is Mr. John Bray, and the offices are at 125, Fleet-street, E.C.

SATURDAY last was a high day and holiday for the residents of Bedford Park, or Bedford Village as it should have been called, at Chiswick. The foundation-stone of the new church in course of erection was laid with the usual ceremony by Earl Nelson. We have already fully illustrated the design,* which is a characteristic combination of Late Gothic and so-called Queen Anne detail, the architect being Mr. R. Norman Shaw, R.A., whose picturesque and convenient houses have rendered the "Village" so much sought after by artists and artistic people, there being about 100 families already located on the estate. After the ceremony of laying the foundation-stone, under which a copy of our illustrations of the building with other reports and papers were secreted, a public luncheon was held at the Bedford Park Club, under the presidency of Earl Nelson, and about 150 persons sat down, including many of the local clergy and interested laity and several well-known men in the literary and art world in London. The Queen Anne style for a church was approvingly remarked upon by the chairman as being associated with a period of the history of the English Church to which Churchmen had reason to refer with pride and pleasure; and in a short speech Mr. Norman Shaw promised, on the occasion of opening the church, that he would give an account more at length of the Queen Anne style. The proprietor of Bedford Park, in responding to the toast of "Prosperity to the Estate," dwelt upon the difficulties with which he, as a novice in building matters, had had to contend since the commencement of the estate, now rather more than two years ago. By no means the least of these difficulties were due to the thorough hatred which he found existed between the ordinary speculative builder and the architect on the one hand and between the ordinary lawyer and both the former individuals on the other. Castles in the air were often nothing to the after-dinner dreams in which the speaker had sometimes indulged, during the midst of which probably the rude announcement would break in upon his reverie with commonplace reality that the boiler at No. 9 had burst, or that similar fate had visited the water-pipes at No. 2. But looking at what had already been accomplished since the starting he had nothing to fear that the original scheme would be fully realised. After the luncheon many visitors amused themselves in inspecting the buildings and houses in course of erection.

THE (American) *Plumber and Sanitary Engineer* suggests to life insurance companies that instead of merely hammering at a man's chest to find if he has a tendency to any disease, would it not be well for the medical examiners of life insurance companies to inquire if he has not got a cesspool leaking into his well, or untrapped pipes beneath his basins and closets? More persons die of zymotic diseases than from almost any other malady, yet a man living in the midst of contagious influences, and hence daily liable to take diphtheria or typhoid fever, would yet find little trouble in getting a heavy policy on his life. If insurance officers would give this subject their attention they might save many losses to their companies, and also benefit the public generally; for if men found that their homes were rated as "hazardous," they would soon begin to think of finding a remedy for the difficulty.

Holloway's Ointment should be well rubbed upon the pit of the stomach and region of the heart in that particular form of indigestion which gives rise to palpitation, shortness of breath, and a suffocating sensation. Every distressing symptom soon yields, digestion becomes easy, the spirits light, and good health returns.

CHIPS.

The memorial stone of a new coffee-house was laid last week at Bangor. The cost will be about £1,500. Mr. Richard Davies, of Bangor, is the architect, and Mr. E. Williams, of Garth, the builder.

A Transatlantic sanitary engineer, in his report on some highway improvements and repairs recently stated regarding a point on the route near a small stream of water that "it was a good place to put down a culvert!"

On Saturday afternoon the memorial stones of a new Wesleyan Methodist Chapel were laid at Newton Heath. The design is modern Gothic, and it will be built of brick, faced with Burnley parpoints, with Halifax stone dressings. It will have a stone spire rising to the height of 130ft. There will be three vestries. The chapel is designed to seat 850 persons. The cost is £8,500. Mr. A. W. Smith, of Manchester, is the architect, and Mr. Henry Brown, of Hollinwood, the builder.

Lord Wolverton has been making great improvement in his kennels at Iwerne-Minster. Claridge's patent asphalt has been laid to all the kennel floors and approaches, with a view of rendering them watertight, which is so essential a matter for hound's feet. The work has been entrusted to Messrs. G. Smith and Co., of London.

A new Wesleyan Chapel was opened at Askerne last week. Mr. Jno. Wells, of Derby, is the architect; and the chapel has been built by Mr. Perry, of Castleford. There is accommodation for nearly 400 persons, and a school has been built at the back for 100 children, with other offices.

The Inter-oceanic Congress has adopted, by 89 votes against 8, the proposal in favour of cutting the canal through the Isthmus of Panama.

Thorton Church, Norfolk, is about to undergo a thorough restoration. Sir Reginald Proctor Beauchamp, Bart., repairs the chancel at his own expense, and the funds for the nave are being collected by the vicar, the Rev. C. B. Ratcliffe. The plans have been drawn out by Mr. Herbert Green, architect, of Norwich.

The Wilts Archaeological Society have arranged to hold a three days' congress at Marlborough, on Tuesday, Wednesday, and Thursday, the 12th, 13th, and 14th August. Marlborough will be visited on the opening day, and the programme for the second day includes a visit to Ouse-hill, Wans' Dyke, the earthworks at Hurst and Saverne House, and on the closing day Rockley, Barbury Castle, Avebury, and Silbury will be visited.

A parochial industrial exhibition was opened in the schoolrooms of the Church of St. John the Divine, Camberwell-new-road, on Tuesday. The exhibition is one of the first of the kind held in the metropolis, and has been divided into two sections, one open to persons of all ages residing in the parish, and the other to children under education in any school in the parish. In the first section there are 10 classes, including specimens of models, carving, turning, furniture, inventions, and designs, paintings, penmanship, and illumination, needlework and fauery-work, shown by some 160 exhibitors. The second-class includes 13 classes, with 200 exhibitors of models, carving, drawings, paintings, maps, knitting, needlework, &c.

Mr. Joseph Storey, who was last year returned by St. Luke's Vestry as their representative on the Metropolitan Board of Works, but whom that body unavailingly requested to resign on account of certain business transactions in reference to the Golden-lane improvement, has at length resigned his seat at the latter body, having failed to obtain re-election to the vestry.

A correspondent of the *City Press* calls attention to the desirability of furnishing the four vacant pedestals at each corner of Blackfriars-bridge with colossal statues of some kind, in order to complete the original design, and points out that the Bridge House Estates Committee of the Corporation have surplus moneys in hand from the fund appropriated to the construction of the bridge, a portion of which should be applied to this purpose.

The third annual Fine Art Exhibition was opened in the Albert Institute Buildings, at Dundee, on Saturday, by Sir Daniel Macnee, P.R.S.A. The present is the largest display of pictures yet made in Dundee: 335 are hung on the walls, and between 200 and 300 were rejected. In the lecture hall of the free library, a supplementary industrial exhibition is being held.

On Sunday week a new Roman Catholic Cathedral in New York, situated in South-avenue, between Fifty-first and Fifty-second-streets, was dedicated by Cardinal McClosky. The corner-stone of the cathedral was laid in 1858, and it has been built at a cost of 4,600,000 dollars; it is entirely constructed of white marble, and measures 334ft. long and 174ft. broad; there are two spires, each 334ft. in height.

A month since the Malton Local Board of Health appointed a Mr. J. F. Buckham from a list of 130 applicants to the combined offices of road surveyor, nuisance inspector, and inspector of buildings, and the Local Government Board has since confirmed the appointment. On Wednesday week the clerk reported that they had "come to a dead-lock, as the surveyor appointed was not able to make his appearance at the time specified, and he was now so poorly as to be unable to attend to business." A discussion on the cause of the new official's illness led to a motion being made, "That Buckham be dismissed in consequence of certain irregularities which have come to our notice." An amendment that he be allowed to resign was proposed; but the original motion was carried, and the members of the board will, a second time within two months, have the privilege of selecting an officer.

The foundation-stone of the permanent church of All Hallows, Southwark, was laid on Wednesday. The church will accommodate 1,200 persons, and will cost about £10,000. It is of the Middle Pointed style, and is being erected from the designs of Mr. Gilbert Scott, M.A., F.S.A. The builder is Mr. Higgins.

An exhibition of oil and water colours was opened at the Academy of Arts, Milsom-street, Bath, on Tuesday.

A new Primitive Methodist Chapel, seating 1,000 persons, was opened at Blacnavor on Sunday.

We are desired to state that the gratings for St. George's Cathedral, and illustrated in our last issue, were not executed, as stated, by Messrs. Farmer and Brindley, but by Messrs. James Stevenson, of the Darlington Works, Southwark-street, who presented them to the church. The models only were prepared by Messrs. Farmer and Co.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Royal Institute of British Architects. Paper by Edward P. Anson on "Recent Excavations of the Roman Forum," 8 p.m.

Society of Engineers. Paper by Charles T. Alford on "The Mineralogy of the Island of Sardinia," 7.30 p.m.

FRIDAY.—Royal Institution. F. J. Bramwell on "The Thunderer Gun Explosion," 9 p.m.

SATURDAY.—Royal Architectural Museum Sketching Club. Excursion to Stone Church, Kent.

Trade News.

WAGES MOVEMENT.

SWEDEN.—A strike among the men employed at the saw-mills at and near Sundswall began on Tuesday, the 27th ult., owing to the refusal of a demand for higher wages. It now extends to 19 saw works and 5,000 workmen, and is still increasing.

THE SLATE TRADE IN NORTH WALES AND IN AMERICA.—Mr. W. J. Parry, the president of the North Wales Quarrymen's Union, who is travelling in America and Canada seeking the best field for the employment of the unionists who have been assisted to emigrate, owing to the stagnation of the slate trade, has forwarded to the Executive Council of the Quarrymen's Union a lengthy report, in which he expresses his conviction that it is useless for common labourers or quarrymen to go to America to seek work in the slate-quarries, wages being extremely low, and work difficult to be had even at that low rate of wages. The condition of the American quarryman he describes as being miserable, the wages of labourers averaging 4d. per hour, and those of quarrymen 6d.; but many of them, owing to the severity of the weather, have been unable to earn anything for three, four, or even five months. One of the matters which excited his surprise was to find that the Welsh were rapidly losing their hold of the art of slate-working, and that comparatively few Welshmen were now employed in the American quarries. He recommends intending emigrants to turn their attention to agriculture.

Douling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to

THE BUILDING NEWS.

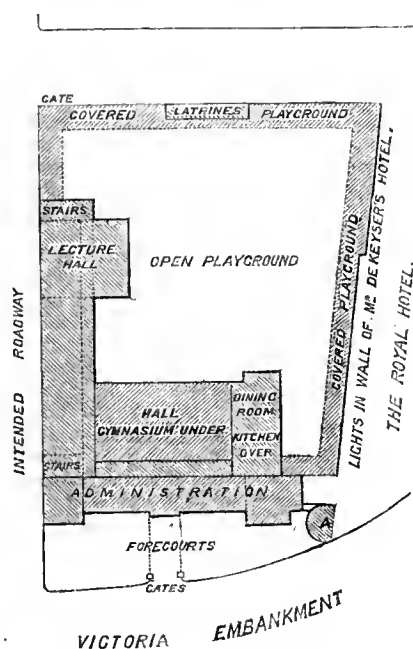

LONDON, FRIDAY, JUNE 13, 1879.

THE CITY OF LONDON SCHOOL COMPETITION.

WE are able to give some further information respecting the above competition this week. We wish we could have announced that the committee had seen fit to withdraw the unwise restriction placed upon the exhibition of the designs, and had called in the services of a professional referee, as in simple justice to the competitors they were bound to do. Strange to say, the members of the committee and their officials individually profess perfect willingness that the designs should be seen by the representatives of the professional Press, but as a body they decline! They have, of course, been unsuccessful in their attempt to keep the profession in the dark—so far, at least, as we are concerned; they have only succeeded in renouncing our criticisms of the designs to a certain degree incomplete and imperfect—the necessary consequence of our brief inspection of the plans. We appeal once more to the committee, and, failing them, to the Court of Common Council, to take the course adopted by every public body in connection with competitions, and thus put an end to the ugly rumours of unfairness and favouritism which are afloat. The building they propose to erect will probably be the type for the next generation of similar erections all over the country. Middle-class education must shortly become a leading question among those which await their solution at the hands of statesmen and social reformers; architects will presently be called upon to design the necessary buildings, and just as the first schools erected by the London School Board became examples of what to imitate and what to avoid for the rest of England, so will the building about to be put up on the Thames Embankment stand as a precedent and model for others of its kind. All the more reason, then, is there that it should be as perfect in plan and design as public criticism can make it, and that the architect entrusted with its execution is likely to prove capable of accomplishing the task entrusted to him. So far as the design placed first is concerned, there is every reason to be satisfied. The information we gave last week was correct. The authors of the design marked "Live and Learn," are Messrs. Davis and Emmanuel, of Finsbury-circus; of "Simplicity," Mr. T. Chatfield Clarke, of Bishopsgate-street; and of "Playgrounds," Mr. T. E. Knightley, of Cannon-street.

"Live and Learn" adopts a mode of distribution in the blocks which we have ventured to call the "irregular" or unsymmetrical; but as we have engraved the block plan it is unnecessary here to enter into detail. The principal entrance forms the centre of the Embankment façade, and gives access to a wide hall 19ft. wide by 15ft. in height in the "administration" block. This is mainly divided into secretaries' offices, committee and waiting-rooms on one side, and on the other into the porter's room, book-store, library, and head-master's room. These communicate with each other. We certainly like the general arrangement of this part. A corridor at the back gives access at one end to the dining-hall, and at the west end to the teaching block, which runs along the western side, by which means the administration is practically separated from the teaching apartments, while the cuisine of the establishment is placed out of

the way of the latter. Another point of architectural significance is that the administrative block forms a single-story range, allowing the large hall, which is made to form the central feature, externally to appear above it as the main block of the composition. The grouping of the recessed hall, with the lofty pavilion-like wings which form the termination of the administration block, and the towers in the inner angles, is very pleasing; while the main front is sufficiently recessed, the authors observe, to avoid building over the underground railway, and also to obtain a garden in front. In referring to the teaching block, which is located along the western side of the site facing the intended roadway, the authors observe with truth that this position secures quiet in the class and lecture-rooms, while the teaching department is kept together, and there are other considerations in connection with the adjoining hotel, as light and air, which render this side better than the eastern for this department. The head-master's rooms are at the south-west corner, and in communication as required, while the rest of the wing is occupied by 7 class-rooms adjoining each other on the ground floor—

nine on the first floor and three above. We observe the hat and cloak lobbies, one to each room, are divided from the several rooms by screens 6ft. high, and, with the class-rooms, are under control. The stairs are arranged at the ends of the teaching block, and give access to the several floors, latrines, and playground; the science department occupies the second floor, and the lecture-hall at the north end, 56ft. by 48ft., is well planned on the isacoustic principle, and has an octagon lantern light, while it is in convenient communication with the laboratory and apparatus room. The authors obtain all their class-rooms above the ground floor level, and one decided merit in the arrangement is that the plan gives a large area for covered and uncovered playground—a very important point in city schools. The hall, 90ft. by 50ft., on the first floor, forms a striking feature in this design, and is placed in immediate communication with the main entrance corridor, one flank facing the Embankment, and the other the open playground. On both sides it is pierced by a series of square-headed mullioned windows, and is lighted besides by windows at the ends, and three dormers on each side of the open timber roof. The treatment of this fea-

ture, internally, is dignified and characteristic; the authors have followed in the roof and details the Renaissance exemplified in the Prussian and Austrian schools. Five entrances are provided. Two of these give access from the class-rooms, and on the south side are three other doorways surrounded by pilasters and entablatures. A gallery is provided at the west end accessible from the staircase landing. We observe the walls are wainscoted and relieved by tablets beneath the windows, while wide hammer-beam principals of semi-Gothic character, with curved ribs, spring from pilasters against the wall. The very elaborate and carefully prepared report accompanying this design proposes foul-air outlets near and in the roof, with warmed fresh-air admission behind the wall linings, communicating with external flues at the floor level. As regards external designs, the authors have wisely selected the French Renaissance of a moderate type, avoiding the excesses of the style; the main block, the hall, and the side wings are symmetrically disposed; the hall is crowned by a high-pitched roof hipped at the ends, with a central flèche, while the advancing wings contribute to give a pleasing, well-broken, yet dignified front to the Embankment. The materials proposed are red brick, with Ancaster stone dressings and green slate roofs. One feature in the design worthy of notice is the proposition to mask the unsightly end of De Keyser's hotel by a semicircular building, which might be appropriated either to the school or to the hotel. Such are the main features of the design placed first by the Committee.

"Simplicity" is based on a central open quadrangle and cloisters, the class-rooms being disposed round on the north, east, and west sides, while the south side is taken up by the hall, which, like the last, forms an important part in the elevation, with the administration and official department in front. This distribution is essentially a Gothic one. The plan shows a rectangular disposition of the buildings, which extend all round a quadrangle about 80ft. square, cloisters with glazed openings on two stories surround this area, and afford communication, light, and air. On the east side are a masters' common-room, lavatory, stairs, and a range of class-rooms, with dining-hall above, outside which a space for tradesmen between the school and hotel is obtained; on the west side there are two blocks of class-rooms, with intervening cloak lobby, head-master's apartments, stairs, and library. Two doors close the front cloister at its ends from the side cloister; the secretaries' rooms are placed on the west side of entrance-hall, and the lavatories on the other. The administrative block in front has its own passage communication, and is well separated from the teaching department; and the dining-room and serving department are conveniently placed on the east side in the rear. At the angles of the cloisters are square rooms for hats with lift; a playground of the whole width of ground at the back by 96ft. from north to south, with covered space on the east side, is obtained. The ground plan presents in outline a rather irregular appearance on the west side from the position of the breaks; the front elevation is symmetrical in the main features, and set back from the Embankment. We have heard this design contains the largest cubical space per boy in the class-rooms, and the smallest cubical space estimating the whole of the building; but of these facts we hesitate to speak confidently. The hotel lights are not interfered with appreciably at all, owing to the space left on this side.

The author of "Playgrounds," the third design, has arranged his plan skilfully as regards the levels, keeping it away from the hotel about 50ft. The playground space is larger than either of the two former—the first having 45,000ft., the second about

21,000ft., and "Simplicity" 49,800ft. The author proposes a central hall, with class-rooms on each side. The entrance-hall has the head-master's, committee, and secretary's rooms on one side, with visitors, masters', and ladies' room, &c., on the other side. The staircase opposite entrance is a spacious one, leading to galleries and first-floor. The large hall on the ground level, with galleries accessible from the upper floor, has its walls pierced with arched openings, two of which are opposite each class-room, and by this means the side corridors, which are 10ft. wide, are lighted. The lower part of these openings are intended to be filled with ornamental sliding screens to confine the ordinary traffic to the corridors. The hall is proposed to be lighted by windows along the sides and ends. Each class-room has its screened lobby for hats and cloaks. The lecture-room is placed on the first-floor, with the other allied apartments *en suite*. The kitchen is placed on the upper floor over the dining-room, and the sanitary details have been carefully considered; every fire-place has a double flue—one half for smoke, and the other for ventilation. The author has adopted the French Renaissance of a collegiate type, and the estimated cost is £53,800, though we understand the cubing of this design has been calculated at 9d.—certainly a high figure if the covered playgrounds are included. We may here describe the general feature of a few other designs.

Last week we spoke of "Concentration," in which the great hall, 125ft. by 64ft., forms the centre, surrounded on three sides with open arched corridors. The orchestra is placed at the south end in a recess; the class rooms are arranged in pairs on the ground floor, with hat lobbies between; the dining-hall is a long apartment, occupying the rear at the west angle, while the other apartments occupy the usual positions. We note, moreover, that the science room is placed at the back of the hall, and is a rectangular apartment, with a circular roof, placed transversely, with curved seats, and the lecturer's desk in the centre of side. Class-rooms are arranged along the front, facing the embankment, not perhaps the most desirable position. We have already generally described the external elevation as being in a Renaissance style, with detail of English character. Another plan, based on the irregular system, bears the motto "Practical." The general distribution of the plan is a rectangular block, with a quadrangle in the centre, surrounded by corridors; on the south side are placed the official rooms, on the west and north sides are the class rooms, while on the east side is the great hall, lighted at the side and ends. The author considers this location the best as regards lighting, and believes a central hall objectionable, as it would be "impossible to avoid dark and ill-ventilated rooms and passages." The western side is occupied by a very long wing, extending to the end, comprising class-rooms, accessible from a long corridor, partly lighted by quadrangle, with a dining-hall at the north end, and a porter's dwelling. A large playground is obtained in the north-east portion of site, with covered ways. We observe the author sets back the east boundary of his buildings about 30ft. from the hotel. The style selected is a modification of the 13th century Gothic, which the author believes, from its simplicity of detail, well adapted for a school. Red brick, with red Mansfield stone, are suggested. We have little space left to enter into the details of this design, and must reserve further remarks. The author estimates his design at £57,000. There is also another design bearing the same motto, whose authorship we recognise at once, and to which we shall refer another time, simply saying now that it is a very good one.

Under the motto "Quis," the authors submit two plans, the chief feature of one being

a central hall with a playground beneath surrounded by corridors which communicate with four groups, and class-rooms obtained at the angles, and forming front and back blocks. The administrative department is in front, with a central hall and staircase. The official rooms are placed on the east side of entrance and the library and head-master's room are arranged *en suite* on the other side. A private corridor connects these apartments. Landing on a grand vestibule, a front corridor gives access to the great hall, the assistant masters' and class-rooms, while the two main corridors on each side of hall lead to a lecture-hall on the same axis. The laboratory and chemical department are placed on the west of the lecture-hall, with the dining-room on the opposite side. In style the authors have adopted a type of Renaissance of rather mixed character and elaborate in detail, but marked by considerable merit in the grouping. Brick and terracotta are the materials suggested; the latter is largely employed in the decorative details. An alternative Gothic design shows a lofty central tower crowned by a short spire over the entrance, while the flank side of hall is made an important feature, and has a fleche in its high-pitched roof. The second plan has a quadrangle in front, and disposes the class-rooms somewhat differently.

"Our Boys" is a design similar in its distribution of the official and teaching departments to many others we have mentioned. The school entrances on each side of the centre, and beyond the administrative apartments in front, open into corridors which surround an open quadrangle, and give access to class-rooms on both sides on the three floors. The hall and dining-room are on the ground floor, approached by the end corridor; the former has five entrances, and has a gallery, while the south bays are designed as a triforium and clerestory, and, by the aid of movable screens can be extended to the width of corridors on both floors. The classification of the school has received attention, and the author has adopted Gothic of the 15th century, as being associated with the foundation of the school in 1440, and as being different to the style of the buildings of the London School Board. Red brick and Portland stone dressings are proposed, and the estimated cost is £57,500.

The following architects are among the competitors:—Messrs. Wm. Ward Lee, Robert Walker, J. P. Seddon, H. S. Legg, T. S. Collett, Thomas Harris, E. C. Robins, Tarring and Wilkinson, J. D. Mathews, Lacy W. Ridge, Wilson and Aldwinckle, T. Roger Smith, Flint Clarkson, Newman and Billing, and Edward Clarke.

While admitting the superiority of one of the three selected designs, we cannot express so favourable an opinion of the others. The committee have certainly placed a good design first. If it is the best of the fifty-three, why not throw the others open for inspection?

THE IPSWICH MUSEUM COMPETITION.

THE town of Ipswich is going in for architectural improvement with a will. The designs for the Museum, Library, and Art Schools have quickly followed those of the new Post-office, recently reviewed in our pages. A capital site has been acquired facing the High-street, and through the exertions of a few of the leading townsmen the idea of erecting a building in which these three great wants of an intelligent community may be combined has so far been carried to a practical issue. Having examined the plans for the Museum, on view during the past week, we can say that the committee are to be congratulated on the professional response to their invitation. Although only ten designs have been sent

in, they are all above the average. No decision has been made at present, but the committee have held one or two preliminary meetings for the consideration of the plans. Of the ten designs, three deserve to be placed foremost as regards plan—an element which in the present case should have primary consideration. Among these "Simplicity" deserves notice for the compactness and economy of his departments, and the avoidance of passages and corridors, if we cannot say so much for the rather pretentious style he has adopted. We may describe the plan as being a rectangle of oblong proportion, with a central hall, entrance and staircase in the shorter axis. The hall forms an elongated area in the middle, and may be objected to as being rather too large, though, in justice to the author, it must be observed the space is used as part of the Museum, groups of sculpture and other large works of art finding here a fitting reception. The reading-room and library are arranged in three compartments—on the south side, and are *en suite*. These are well lighted from windows in the outer wall. On the right of hall a corresponding arrangement of the main walls provides for a class and lecture-room 46 × 24 in front, and a laboratory of similar size behind, and these apartments can be entered from a separate north entrance (for the use of students) in the return side of building, or from the central hall. The chief objection we find to the plan is the position of laboratory, which would be better in a more isolated part of the building. On the first floor the main walls are carried up so as to produce the same general division. Landing in a large central saloon or museum, lighted by a skylight, the visitor may pass through a series of apartments on the south side, in all respects like those below, one opening into the next. These are devoted to the museum. The front and back rooms are each 46ft. × 24ft., divided into bays by cases; the intermediate room is 33ft. × 26ft. They are lighted by windows and skylights. From the same landing the painting and class-rooms are entered, a short passage—the only one in the whole building—giving access to the rooms. It will thus be seen the Museum and School of Art form, practically, a range of apartments *en suite*, but on opposite sides. A masterly and sketchy perspective in pencil accompanies this set, the author adopting Renaissance with a centre crowned by a quadrangular-shaped dome, the remaining part of façade having pilasters of two orders. Between the windows of the ground and upper stories are a series of panels with subjects in relief; the lower pilasters have medallion panels at the top for heads representative of Science and Art. Pressed red brick and Ancaster stone dressings are proposed for the front—two good materials—but we think the design, though an able one, is too expensive in the materials specified; at all events, we object to the terminals along the top and the scrolled ornamentation of the upper window-heads. An alternative sketch in a Gothic dress, showing a centre fleche, is sent, but the treatment has less to recommend it, and the pointed arches in pairs are rather ecclesiastical in spirit. No plan has economised its wall-space so well as this one.

"Sivez Moi," whose authorship and motto we detect as being the same as that of plans sent in for the Post-office competition, shows a well distributed and skilful plan, though on a different principle to the last described. On the ground-plan the free library and reading-room and the science and art schools form two wings, entered from a centre vestibule, which makes a projecting block, the buildings being somewhat of the shape of a letter *u*. The building is proposed to be entered by a low porch and flight of steps, which leads into a spacious

vestibule, 24ft. by 24ft. Through a doorway on the left side a corridor runs along the front, giving access to the patent library and committee-room, the librarian's room, and to the reading-room and library, each 42ft. by 24ft., which last named apartments form a return end wing to the building, lighted at the sides and at ends. The north or right-hand wing is devoted to the science and art schools, and is entered through a similar doorway from the vestibule. The laboratory is placed at the back, filling up the space between the vestibule and the north wing, and is approached by a glass corridor and lobby, and areas for light and air well separate it from the front. The crooked corridor entrance leading from the vestibule to the school department is somewhat objectionable, but the departments are well separated, while the centre hall forms a common but distinct feature. On the upper floor the plan is enlarged by extending the museum between the library and vestibule blocks at the back, thus forming a quadrangular arrangement, with a central area for light and air. This has been effected by arching below the open space on the south side, an arrangement rendered practicable by the fall of the ground, though, on the other hand, it rather destroys the symmetry of plan below. Ascending the main staircase in the centre hall, the museum is reached from a half-landing, or from the main landing or saloon over the vestibule, and comprise four rooms *en suite*, arranged as a quadrangle. These are lighted chiefly by flat skylights above a deep cove, and the general effect is shown in a pencil sketch of the interior, and a north light is obtained for the painting-rooms. Externally, the design is treated in a Classic and dignified manner; there is a domical centre, with pediment and advancing wings at the ends, with coupled pilasters at the angles. The receding parts are quite plain, and hardly connect agreeably, but generally the design is characteristic of its purpose, and avoids a wasteful display of ornament, which is confined to a little carving and niches for sculpture between the angle pilasters. A carefully-drawn ink perspective and pencil sketches of the interior treatment accompany the design.

"Bona Fides," is the design of a local architect, and we may here express our regret the author of so good a plan should have made allusions in his description which only a local man could make, and thus have individualised his own work. The design is an economical one in its division, a rectangular arrangement has been adopted. The library and reading room, 60ft. by 34ft., occupy the middle of the area, and are lighted through a circular ribbed glazed roof; the museum is placed along the south side, and is 61ft. by 25ft., lighted by windows along the front with projecting show-cases between; the Science and Art Department is on the north side, and has its own entrance, and the laboratory is placed behind. An alternative plan shows the museum in the centre and the library on the left, a rather better arrangement in some respects. We do not see any communication from the gallery, which surrounds the enclosed library, with other parts of the first floor; but there are two spiral staircases provided in the angles to connect the main floors. In the sections, which are very creditably drawn and tinted, we observe the light is admitted at such angles as to avoid "glitter points," very essential to be observed in museums and galleries of art. The design is treated in red brick, with carved panels between the windows of the main stories, it has high roofs and chimneys well broken, and is in a Seventeenth Century style rather more Renaissance than Queen Anne, though the chimney springing out of a dormer on the south side would almost suggest the vagaries of the last-named style. A vigorously-drawn line perspective is sent in, and the

style of the drawings leads us to the conclusion that this and "Postage Stamp" in the last competition are by the same hand. The author submits a builder's tender to execute the work for £6,932 (why not £7,000?)—the last-named sum is little enough. Of other designs marked by considerable merit in the planning, we may name "Architect" as a compact arrangement, in which the museum is placed behind in a central position, the library and reading-room being on the south side. On the first floor the museum extends over the south wing of library and reading-room. We do not like the areas cut out of the museum by the lavatories; there are, nevertheless, a few good points in the plan, and little waste room, albeit the entrances are a little crowded. We cannot speak with commendation of the elevations. One in a Queen Anne style is spoilt by the projecting wings, with chimneys in the gables of unmitigated plainness. The back and sides are meanly plain. Another design is in a more finished species of the style, and the detail is better, the entrance forming in both elevations an arched terrace between the wings, but the west elevation is bare to ugliness. Its plan shows an arrangement in three parallelograms, the centre being the museum opposite entrance 55ft. x 33ft., a reading-room and library on the south side, and the school department on the north. The entrances and hall conveniences are not satisfactory. We believe the author of this has been the winner of the Corn Exchange prize.

"Patti chiari, amicizia lunga" adopts a more irregular plan. The museum is 93ft. by 35ft., and forms a flat, single-storied apartments, apparently too much cut off from the rest of the building on the south. The main entrance in front leads to a wide, lighted corridor, which runs along the structure at the back and gives access to the library and reading-room on the north side of entrance, with a curator's room between the latter and large museum. This distribution is less economical certainly than the more concentrated plan, which places the museum or the reading-room in a central portion of the ground. On the first floor we find the science class-rooms are arranged in front, entered from a long back corridor over the one below; the painting and model rooms are, as usual, in the north wing. The laboratory is placed behind opposite entrance. A domestic type of French Gothic is chosen, a pair of small gables and a projecting oriel from the science-room being the principal features in the façade. The elevation is certainly cleverly treated, and does the design more justice than the perspective. In "Pinpatch" we recognise, partly by the altered prefix, the same hand as in "Despatch" in the Post-office competition, and the author is one of the few who have adopted Gothic, and this time is more successful. Unlike the last-mentioned, a Late Tudor treatment has been chosen, a style certainly that has some claim to be employed in a brick locality, although it is rather suggestive of a collegiate character than a building devoted to mixed secular purposes. It is broken in front by a centre gable with oriel over the entrance and projecting wings; dormers with pinnacles break the roof line, and red brick in black mortar relieved by cross bands of dark brick in the sides form the chief ornamentation. The plan adopts the three parallelogram principle, a mode of dealing with the site that seems to have found favour with some of the committee. The museum, 80ft. by 30ft., surrounded by galleries, lighted from the roof mainly, makes the centre parallelogram, on either side of which are the conveniences, &c., while the parallel lateral wings are devoted to the other departments, the reading-room and library being on the south side. The laboratory is well isolated in

rear, and the science class-rooms are in the north wing. Double stairs are shown, one to each side; these and the conveniences are well studied, but the entrance is poor. On the upper floor the museum is extended over the library, and open lighted areas are obtained between the blocks. A carefully-drawn perspective accompanies the design, which certainly is not flattered by the elevations. The chimneys at the sides are unpleasantly twisted, and the pinnacles would have been wisely curtailed.

Two other designs demand notice: one is "Economy." The museum is made the centre feature, and is 60ft. by 40ft.; on the south side the library and reading-room are dovetailed into each other, an arrangement that is made to facilitate in the superintendence of these rooms, enabling one attendant to command a view of both. The museum has a circular roof of iron and side arcades of the same material, which also carry the gallery. The natural history museum is assigned the first floor in the south side. There is a corridor entrance to science school on the ground floor, also above to the art rooms, and some skill has been shown in the convenience of communication and classification. The exterior is well grouped, but the treatment of Renaissance character resembles a country residence more than a public building. "Pro Bono Publico" is the motto of an able design, the author of which submits two elevations, one in Classic, a plain, sensibly-treated, and compactly grouped building, and another in Gothic. The museum is a central apartment, facing the main entrance, with the library and reading-rooms forming wings on the south side; the main fault of the plan, otherwise ingenious, is that the doorways to reading-room and museum are not sufficiently under the control of the curator. The advanced class-rooms are well lighted by a north light, which enters through a curved pointed shaped roof. The Gothic is certainly the best of the kind submitted, as the author has avoided both the ecclesiastical and domestic types, and has imparted a thoroughly secular character to his design. We have space only to refer to "Veritas Vincit," a design in the Gothic, but of too school-like a treatment, and uneconomical and ill-considered in arrangement. The museum is undesirably placed at the north end on first-floor, and the schools are below. "Work and Win" is an elaborated plan in a similar style, giving much more than is wanted, and a little too ingenious in its octagonal vestibule and centre octagon-ended museum. The design occupies the whole front apparently in its length, and the roofing and gutters are particularly costly. Another design we saw looks more like the work of a plasterer, but it had no motto, while its design cannot be seriously criticised.

It will be observed from these remarks that there are three or four designs of considerable merit, and which the committee may fairly take as embodying all their wants. As in the Post Office, so in this case, the sum of £7,000 is inadequate, and it is not possible to carry out any of the designs as they ought to be executed for this sum. Our inquiries convince us, however, of the very limited resources of the committee, and that economy of construction must be first considered in the adoption of a plan. One or two of those we first mentioned, in which the departments are grouped round a central museum or vestibule, appear to afford the best chance of obtaining this. Unnecessary corridors lead to increased interior walling, and we should give preference, *ceteris paribus*, to the arrangements which dispense as much as practicable with interior passages and waste areas. A museum broken into several rooms with a vestibule forming a part of the suite, is more desirable for classification and study, than one long or large

gallery; another consideration should be the facility the plan affords to separate the schools from the public portion when necessary. The laboratory should if possible be isolated or nearly so, while of other essentials to economy, good lighting to the museum, reading-room, and class-rooms is of primary consideration. We understood the scheme originated with Dr. J. E. Taylor, the present curator of the museum, a gentleman whose scientific attainments are widely known; Mr. Westrop, a member of the Committee has been another moving spirit to whom the funds subscribed are mainly due; the plans submitted are creditable to the competitors, and under these circumstances we hope the Committee, who appear to have fairly courted inquiry, will select a design worthy of the town, and the energy that has been thrown into the competition.

EXHIBITION OF WORKS IN BLACK AND WHITE.

THE present exhibition just opened at the Dudley Gallery, though it sustains the reputation this collection has always enjoyed, is scarcely remarkable for any very striking work. We miss the contributions of several familiar contributors, Mr. Hubert Herkomer being one of them; on the other hand, the drawings are, technically speaking, above the order of merit we have previously remarked. Subjects in chalk, charcoal, lampblack, and sepia, abound, while there are many etchings of much beauty. Illustrations of journals and works of fiction as usual occupy a large space, and we have some excellent original sketches by W. Small, Percy Macquoid, Samuel Read, Charles Keene, H. S. Marks, R.A., Linley Sambourne, J. Tissot, E. J. Gregory, A. C. Corbould, and others, contributed to our contemporaries the *Illustrated London News*, the *Graphic*, and *Punch*. Thus Mr. W. Small's illustrations to "Under One Roof," a serial tale, in lampblack and white, thickly handled, are clever in composition and drawing, often humorous. We mention particularly of this series, Nos. 6, 263, 281, 327; Mr. Percy Macquoid's "Lucky Doz," Mr. Samuel Read's design (No. 29) in Indian ink; Mr. C. Keene's "Ploughing the Main" in pen and ink (75); Mr. H. S. Marks' "Finishing Touch" (113); Mr. Watson's "A Dreary Day" (308); Mr. C. Keene's ink sketch (251), and Mr. A. Hopkins' "Garden Party," are all sketches that display skill in design with a free use of the pencil, and many are familiar to our readers. A very spirited drawing in chalk is "Such Witching Looks are Baited Hooks," by Mr. T. W. Wilson. "Kindred Spirits," No. 19, by Mr. Lionel P. Smythe, is a happy idea executed in lampblack and white. The indolent, sluggish-looking boy shown on the swing, listlessly watching the playfulness of two cats, one clambering up a tree by his side, is thoroughly suggestive of the title chosen. The drawing is of considerable depth of tone and highly finished, wanting colour only to make it perfect. M. A. Mongin, in "Deux Eaux-fortes, d'après Meissonier" (30), exhibits two charming etchings with all the expression, delicacy and finish of Bebm and the early German engravers. In a more vigorous style is "Rochers de Douarnenez" (38). (eau-forte), by L. Le Conteux, a rocky coast. H. Pilleau contributes some pleasing sketches in lampblack (40), as also Felix Buhot, in an etching entitled "Aux Champs Elysée" (41). Architectural subjects are most rare, among the few we note Mr. W. H. Stock's sepia drawing of St. David's Cathedral, and Mr. Arthur Evershed's etching of the "Bloody and Garden Towers, Tower of London" (73) the latter careful both in drawing and detail. "Christchurch, Hants," is a capital subject hardly done justice to in the lampblack sketch, No. 53; Mr. C. F. Watson in

"Dawning Day," gives us a hazy but picturesque charcoal sketch of St. Paul's and the river, taken from the Charing-cross foot-bridge apparently. The Shot Tower in the foreground forms a pleasing balance and contrast to the dome, and the subject is an admirable one for treatment in sombre black and white. No. 58, "London from the top of Greenwich Observatory," is a large etching by Mr. W. Edwin Edwards, bold, vigorous, and characteristic, but a trifle too black in the park scenery, albeit the subject is provocative in its spirit of the Latin line, "Fumus et opes strepitumque." A twilight effect is happily produced in Mr. Weedon's "Fittleworth Lock," the poplars against the half-lighted sky make a capital picture, broad and characteristic in treatment. Mr. Arthur Evershed is a very feeling etcher. His "Kingston on Thames" (91) conveys a good idea of a picturesque locality, while the execution exhibits technical power. "Antwerp Cathedral" (93), is one of Mr. W. Crooke's best etchings rendered with considerable skill in detail. We are glad to find the works of Leon Lhermitte still adorn the walls of this gallery, and we may especially point to Nos. 96, 106, 327, and 377, as very fine. "Halle aux Poissons de St. Malo," is one of the largest drawings. It is executed in charcoal, and represents a group of fish-women engaged by buying. The chiaroscuro, like that of all M. Lhermitte's pictures, is excellent, and the grouping and drawing of the figures display quite the hand of a master. It has all the solidity and force of an oil-painting. "L'Épicerie de Morlaix" we fancy to have seen before. The overhanging houses of the quaint old French seaport are cleverly drawn, while before the shop-doors a grocer's gossiping on between some women. "La Visite Pastorale" (327) is another charcoal drawing of a fine Early Pointed church, in which the bishop is giving his benediction to a group of worshippers. For solidity, light and shadow, and grouping there is nothing equal to it in the Exhibition, except the same artist's "Interior of the Church of Mezy" (No. 377), in which we note a very similar detail of stiff-foliaged capitals. Mr. Arthur Croft sends a pencil drawing of "Lago di Varese" (121), a fine bit of scenery and manipulation. Mr. J. Wolf's "An Elephant Abroad" (122) is a clever fancy picture, softly finished in charcoal, yet of considerable energy. It depicts two kangaroos watching the approach of an elephant through a field of thick herbage, barely discerned through a misty atmosphere. "Le Début de la Walküre," G. H. Fautin, is dramatic and forcible. "Proofs of Wood Engravings" (129), by Mr. F. G. Kitton, contains a charming little etching of Ratisbon, from the pencil of H. W. Brewer. "The Path to the Wood," by Mr. Allan Barraud (131), sustains that artist's reputation; while we must not pass unnoticed Mr. River's "Cathedral Porch, Seville" (132), in pen and ink; Mr. Tristram Ellis's "Four Etchings of Cyprus"; Mr. H. Bennett's pen and ink drawing of a poetic incident in the Frog Prince; a sepia drawing of House at Old Bavono by E. V. B.; a clever sepia sketch of a yacht by Francis Powell (169); a study for an illustration; and "October" (179), a highly finished etching by Mr. James Tissot showing a richly silk attired girl picking her way through a bower of chestnut foliage. Two small pieces in sepia, with the signature E. V. B., take the fancy for the thoroughly poetic or allegorical sentiment conveyed. One is the "Last Days of Conrad, Poet and Philosopher"; the old man looks bowed down and meditative; on the books before him are written the word "Nihil," as expressive of his despair; a youth is handing him a volume upon which is the significant word "Spes." The "Heart of Stone" is another sketch in India ink—a legendary

idea conceived and worked out with much skill. The most remarkable of the exhibits are hung upon the end wall of the gallery. Here we have a few designs and drawings of undoubted merit. Mr. H. Holiday, in No. 197—"Studies from a Group for a Decorative Cartoon"—shows a red chalk drawing, the subject being St. Paul's Conversion. Conceived with considerable feeling and truthfulness is Mr. Frederick Goodall's "Study for the Infant Moses" (198). The rounded limbs are admirable in drawing, and well shaded, and the expression of the infant's face calm and dignified. Mr. Walter Crane exhibits four subjects this year, and, as a pencil sketch of an architectural subject, his "Isola de San Bartolomeo with Pons Cestias" (199) must be noted. Mr. E. J. Poynter, R.A., is represented in a few studies of classical figures. His "Study for a Figure of Esculapius" (207), in red chalk, and the sketches for figures and drapery in his great work at the Royal Academy, the picture of Nausicaä, besides a study for the latter figure, particularly call for mention (No. 215). Mr. Edward Burne Jones figures also in some exquisitely-drawn studies (212, 213, 236, 238), drawn in pencil on a dark green-toned ground. His "Studies for a Man at an Organ" are full of poetic meaning; and his frame of "Five Studies" exhibit classical feeling in composition combined with admirable finish; the outline and drapery of the women are drawn with consummate delicacy and grace. In this class we must not pass by Mr. Poynter's "Studies for a Figure of Helen" (239), in which the painter shows three classically-conceived women, though scarcely of that surpassing beauty recorded in the mythical accounts of the Trojan War. Mr. F. Goodall's "Holy Mother" (224) occupies the place of honour. The mother has her hand fondly holding the infant Saviour upon her knee; the countenances of both are inexpressibly tender and softly cast, and the limbs of the Holy Infant mobile and graceful. An ideal sentiment pervades the composition, the figures being relieved by hangings. In execution, nothing can surpass the finish and softness of the piece, which is in black chalk upon grey paper. We cannot pass by Mr. W. E. F. Britten's graceful study for the drapery of Arachne (216), nor Mr. John Medland's view of Trequier Cathedral, Brittany, in pen and ink, the latter a boldly drawn sketch of Norman and Pointed towers and cloister. Mr. Ernest George contributes two of his characteristic etchings. Very picturesque are the old galleried houses on the Ile Strasburg (235) and the "City Ditch, Basle" (399). The first is a charming *bonne bouche* rendered in a remarkably feeling style. We must note also Mr. P. Macnab's "Study of a Head of a Westphalian Peasant" (248), Mr. D. Law's "Peat Moss Head of Loch Awe" (262); "A Cynic," by Mr. J. W. Waterhouse, a study of Athenian life, in sepia. A few bold charcoal drawings by Mr. Seymour Haden, as 290, "A Salmon River" (307), and "In a Wood" (404), are forcible in their handling of light and shade, but all of great depth of shading and Cimmerian in tone. Mr. Fitzgerald's "Jack Frost" (361) is a clever drawing, in which the spectral embodiment of frost is ingeniously introduced; Mr. Arthur Severn's "Moonlight at Sea" (376) is a charming bit of water; Mr. F. Murray, in 401, "The Death of Wood in the days of Iron," tells its story with feeling and effectiveness, while we must not pass "The Vesper Bell," an etching by A. H. Haig (334), and No. 354, "Ailsa Craig," a large and powerfully drawn charcoal view of this grand rock, by Mr. F. Powell; Mr. Frank Dillon's fine charcoal drawing, "Lotus Pools, Japan" (355), suggestive of decoration in the crane on the wing; and Mr. R. Josey's engraving of

"Helen of Troy," after Sir F. Leighton, P.R.A. (427). There are a few others we must mention, such as Mr. Cave Thomas's fine conception, entitled "Truth Foiled at the Door of Prejudice" (478); Mr. J. L. Dollman's clever drawing in charcoal of "Night" (525), and Mr. Watson's "Drury Court" (477), an etching.

PERSONAL AND PROFESSIONAL RECOLLECTIONS OF SIR GILBERT SCOTT.*

[SECOND NOTICE.]

THE period dealt with in the portion of the book we now reach was undoubtedly the turning-point of Sir Gilbert Scott's professional life. In conjunction with his partner, Moffatt, he had obtained a fair practice of its kind, which, in the ordinary course of things, should have expanded in very different directions from that it actually took. Prisons, schools, or hospitals might as a matter of course have been added to the practice of a firm of architects whose business had started with workhouses, but that the senior partner should suddenly devote himself to ecclesiastical architecture with the measure of success which accompanied his efforts can only be accounted for on a supposition which was really a fact, namely, that some powerful outside influence suddenly developed capabilities and aspirations which were but waiting to be called forth. This influence came from Pugin, whose own efforts in the revival of Gothic architecture were so successful, and yet so surpassed, as far as actual results were concerned, by the architect who was to adapt the great art principles which Pugin revived to the needs of a faith with which the latter could have no sympathy. How this came about Sir Gilbert Scott himself tells us.

In 1838, shortly after his marriage, he built his first church at Lincoln, of which he honestly says he can say little in its favour, except that it was better than many others then erected. Six others followed, all agreeing in the meagreness of their construction and the contemptible character of their fittings, in most of them being galleried to the very eyes, and in the use of plaster for internal mouldings even for the pillars. These, as Sir Gilbert Scott admits, "were days of abject degradation," only lasting, it is true, about two years, but he adds—"Alas! what a mass of horrors was perpetrated during that short interval! Often, and that within a few months of this period, have I been wicked enough to wish my works burnt down again." In 1840, however, came the awakening. An acquaintance with the Cambridge Camden Society, and the perusal of Pugin's articles in the *Dublin Review*, followed up by a severe lecture from Mr. Webb, the secretary of the Camden Society, led Scott to become a reader of the *Ecclesiologist*. Pugin's articles in that magazine excited him "almost to fury," and he suddenly found himself like a "person awakened from a long feverish dream." His first longing was to make Pugin's acquaintance. He made an excuse for writing to him, and, to his "almost tremendous delight," Pugin invited him to call. Of Pugin Sir Gilbert says:—

"He was tremendously jolly, and showed almost too much *bonhomie* to accord with my romantic expectations. I very rarely saw him again, though I became a devoted reader of his written, and visitor of his erected works, and a greedy recipient of every tale about him, and report of what he said or did. A new phase had come over me, thoroughly *en rapport* with my early taste, but in utter discord with the 'fittful fever' of my poor-law activity. I was, in fact, a new man, though that man was, according to the trite saying, the true son of my boyhood."

* Personal and Professional Recollections of the late Sir Gilbert Scott, R.A. Edited by his son, G. GILBERT SCOTT, F.S.A. London: Sampson Low, Marston, Searle, and Rivington.

While the awakening was thus commencing Sir Gilbert was invited to compete for the erection of the Martyrs' Memorial at Oxford. He threw himself into the contest with all the ardour he possessed, and succeeded. Of the result, he says that it was achieved before his complete awakening to a true feeling for church architecture, is proved by the defects of the accompanying addition to St. Mary Magdalene's Church; still he fancies the cross itself was better than any one but Pugin would then have produced. Shortly afterwards two other important works came into the office: the Infant Orphan Asylum at Wanstead and the Church of St. Giles, Camberwell. The plan of the first was Moffatt's, the design Scott's. The second building was not erected according to the competition drawing, which was a "very ambitious design, groined throughout with terra-cotta," but was a less costly structure, the result of parochial opposition and a compromise. The first restoration Sir Gilbert undertook was the refitting of Chesterfield Church, where, though working as yet in the dark and hampered by restrictions, he seems to have recovered and retained the old rood-screen which, some years later, the *Ecclesiologist* declared he had sold, and that it had only been recovered by the exertions of the parishioners. The anti-restorationists of our own day, it will be seen, have not altogether enjoyed a monopoly of the capability for exaggeration. Sir Gilbert's real initiation into such work came, he thinks, with the restoration of St. Mary's, Stafford, which after considerable controversy, in which the Rev. J. L. Petit took an active part, he was allowed to undertake. During the earlier part of the work he had the advantage of the services of his friend Edwin Gwilt, the son of old George Gwilt, the restorer of the choir and Lady chapel of St. Saviour's, Southwark. He was conservative to the backbone, and though Sir Gilbert Scott admits that too little actual old work was preserved, he believes that, barring this, no restoration could have been more scrupulously conscientious. The most serious part of the work was the repair of the central tower, the four piers of which had become so crushed, that they had to be almost entirely rebuilt. Dangerous and unenviable work this, but work which Sir Gilbert Scott had so frequently to repeat, that his cautions respecting the same may be well reproduced here:—

"I. Be assured that no amount of shoring can be too much for safety, no foundations to your shorings too strong, and no principles of constructing it too well considered. II. Use the hardest stone for your new work which you can procure, and spare no pains in bonding it, and tying together with copper. III. Be very slow in your operations, excepting at critical junctures, where the very contrary is necessary; be careful in your principle of movable supports, as you cut away old work; set every stone in the very best cement, and run in the core with grout of the same material. IV. Key up well at the top, and leave your shoring a long time after the work is done, and then remove it with the greatest care. V. (Though more properly first.) Tie your tower well together with iron before you begin, and take especial care of your foundations. Above all, have a thoroughly practical clerk of the works, neither too young, nor too old.

"The shoring must be all of undivided timbers, and often of four or more such balks, bound and bolted together into one by irons."

The poor-law work of the firm still continued, but very different buildings were now erected from those with which Scott and Moffatt's practice commenced. The style of the work was usually Elizabethan, and in many cases the designs were really good. Sir Gilbert especially mentions those at Dunmow, Billericay, Belper, Windsor, Amersham, and Macclesfield. Meanwhile the church practice—restoration, as well as new buildings—rapidly increased in quantity and merit. One restoration—that of the beautiful chapel of St. Mary, on Wakefield-

bridge, to which Sir Gilbert says he devoted his best energies, was certainly rendered abortive by one false step, which in later years caused him the "utmost shame and chagrin." The contractor who had been Scott's carver, having a handsome offer made him to re-erect the semi-decayed front of the chapel in a park close by, offered to carve a new one in Caen stone. Sir Gilbert Scott consented to the proposal. The new front, it is true, was a masterpiece of workmanship, but the Caen stone in which it was executed is now more rotten than the old work which was removed to make room for it!

In 1844 Sir Gilbert was induced to enter into the competition for the rebuilding of St. Nicholas' Church, Hamburg. Up to this time he had seen nothing of Continental architecture except during a two days' visit to Calais; he at once, however, made up his mind that the style of his intended design must be German Gothic, and that he must make that style his study. He accordingly set out on his first Continental tour, working through Belgium to Cologne, where he found himself uncertain whether he ought to adopt the semi-Romanesque, of which that city supplies such a field of study, or the complete Gothic of the Cathedral of Altenburg. He was unaware then of the French origin of the latter style, and the phase he ultimately adopted was founded rather on 14th than on 13th century work. His journey had enabled him to catch the general spirit of German work—the drawings were well finished, the best elevations being made by Mr. Coe and Mr. Street, and the effect of them upon the people of Hamburg "was perfectly electrical." They declared that the design was more German than that of any German architect, and though some delay and opposition ensued, the triumph of the English architect was certain. One of the consequences of this competition was a violent attack upon Sir Gilbert at home in the *Ecclesiologist* for undertaking a Lutheran church. He wrote a formal reply, to which—with unfairness equal to their bigotry—the conductors refused admission. It is given at length in the book, and is, apart from all architectural considerations, a well-argued defence of the position of the Lutherans.

In 1849, wholly unexpectedly but to his great and lasting delight, Sir Gilbert was appointed architect to Westminster Abbey, in succession to Mr. Blore, who had just resigned. He at once commenced a careful investigation of its antiquities, and the good fruit they bore is too well-known to need further mention here. A short tour in Italy in 1851, in company with Mr. Benjamin Ferrey, seems to have been a welcome and well-enjoyed holiday. Berlin was first visited, where the affected delight of the hotel-keeper at seeing him was complacently attributed by Sir Gilbert to the fact of his being the architect of St. Nicholas at Hamburg, but his vanity was rudely shocked on discovering that the worthy host had taken him—or pretended to do so—for Sir Walter Scott, the poet. Sir Gilbert thinks he gained much by his Italian tour, but he returned home convinced that Italian Gothic as such must not be used in England, although its study was desirable and indeed necessary to the perfecting of our own art revival. The same year, in conjunction with Mr. C. Bruce Allen and a number of architects, the Architectural Museum was founded. The scheme hung fire at first. "Street discouraged it as tending to copyism, Butterfield gave very cold support, poor Pugin was just laid by." Sir Gilbert, however, went to work with a will, got up a good list of annual subscribers and about £500 in donations, lent his own large collection of casts, and set agents to work to procure new ones. A loft was taken in a wharf at Cannon-row, Westminster, which was soon filled

"There we used to have lectures in the midst of our specimens. There Ruskin has poured forth his most telling eloquence. There we held annual conversations, when 500 or 600 persons were presided over in the cock-loft by the prince-like Earl de Grey, and were addressed often by some of the first men in the country; but, above all, here were our carvers taught their art from the best ancient models, and our students acquired a degree of skill and taste in the drawing of architectural ornament which had never before been reached, nor has (since the removal of the museum) been retained. These were the days of our pride, and I confess that I even now feel a pardonable exultation when I call to remembrance the share I took in bringing about such noble results. No movement ever made in our day, had equalled this in its effects both upon workmen and students. Our cock-loft was the centre of their artistic study and improvement, and to myself and others engaged in the work it was a source of constant and almost daily delight and interest. During my journeys I was ever looking out for objects of art, whose representation might enrich our collection: and even in the gardens, in the fields, or by the seaside, the very leaves and flowers seemed to connect themselves with our art-scheme, and to suggest plans for illustrating all such productions as would lend suggestions to art."

It is not out of place here to remind those who have not yet associated themselves with the memorial to Sir Gilbert Scott, which is now being promoted by those who at present guide the destinies of the Architectural Museum, that the above passage but faintly indicates the interest Sir Gilbert Scott took in this his favourite project. "The vision was, however, soon clouded." In his enthusiasm he had outrun the constable, for heavy debt stared the Museum in the face. An appeal was made to Caesar, and, as usual, Caesar took particularly good care to have his equivalent for the help vouchsafed. A deputation consisting of Sir Gilbert, Earl de Grey, and Mr. Clutton, who was then the hon. secretary to the museum, waited on the Prince Consort, who promised and gave aid, and became the "patron" of the scheme. His Royal Highness favoured the deputation with a *réchauffé* of one of Mr. Cole's lectures on the contemptible state of architectural education in England, and referred them to Mr. Cole and Mr. Redgrave, who took up the case with some favour, the result being an annual subscription of a hundred pounds, on the condition of the free admission of the students of the South Kensington School of Art. The ultimate result need not be further referred to. South Kensington for a time swallowed up the Architectural Museum; "students were frightened away by distance and red tape." And although, later on, these annoying circumstances were, as Sir Gilbert Scott admits, much mitigated by the noble collection brought together under the same roof by the Science and Art Department, and the first-rate art library since added to it, no one can doubt that the subsequent emancipation of the Architectural Museum was a healthy return to the principles of independence and self-support which contributed to its establishment. Let those who are now responsible for its maintenance bear well in mind the lesson taught by the "Recollections" Sir Gilbert Scott has left behind him.

We may pass more rapidly over the remaining pages of the book, because the events with which they deal are, for the most part, familiar to our readers—at any rate, to those whose acquaintance with this journal dates from its foundation. There are, however, one or two important matters which must be noticed, the first being the dissolution of the firm Scott and Moffatt, in 1846—a step Sir Gilbert Scott had long desired to take, but to which he was only ultimately spurred on by the importunities of his wife—and the next the competition for the Government Offices, in the autumn of 1856. As usual, the competing architects got little but vexation and disappointment for their pains. The original scheme fell through altogether, and after much delay, in 1858 Sir Gilbert Scott was appointed architect for

the Foreign Office, and Sir Digby Wyatt for the India Office, in conjunction with him. The designs were made, and working drawings ordered and proceeded with, when Sir William Tite commenced a violent opposition in Parliament aided by the support of Lord Palmerston. Possibly, had the Tory Government remained in office Sir Gilbert might have pulled through, but the general election of 1858, which resulted in the return of Lord Palmerston to power, destroyed all hope. Palmerston sent for Scott and told him plainly that he did not want to disturb his appointment, but that he must insist on an Italian design. Still Sir Gilbert struggled on with such "faith in Gothic" that he always believed "something would turn up in its favour"; the ultimate result in 1860 being a total alteration in the arrangements with regard to the building, and a threat on the part of Lord Palmerston to cancel Sir Gilbert Scott's appointment if he did not conform to his lordship's art notions. With excessive regret and sorrow Scott had to give in, his consolation being, as he says, "The public seemed to understand my position and to feel for it, and I never received any annoying or painful rebuke, and even Mr. Ruskin told me I had done quite right."

Sir Gilbert apparently was a believer in ghosts. He took a house in the Isle of Wight on the very edge of the Chine, and in his book simply says that "the house was haunted." Mr. G. G. Scott corroborates the story. Footsteps used to be heard on the verandah, and the boys of the family set themselves to detect the ghost, but in vain. All the usual infallible methods of catching such creatures were tried without effect. Of course, they soon found out that other visitors had been similarly frightened; and then a story came out about a wicked uncle who murdered his innocent niece and ward in a cellar, and who, for his sins, was let out of Hades to pace the flagging where he was used to walk. These stories always turn up after the ghosts begin to haunt the scenes of their crimes, and the experience of Sir Gilbert and his family seems to have been precisely that of other people who have been similarly deceived.

Among the personal recollections which follow are those relating to the bereavements of Sir Gilbert's later life, the death of his son, his sister, his wife, and others; among those having reference to professional matters are the records of his share in the New Law Courts Competition, his "great failure," the erection of the Prince Consort memorial, the St. Pancras Station, and the various cathedral restorations with which he was concerned. The volume closes with some remarks on the Queen Anne style and the Anti-Restorationists of a sensible and practical kind, and altogether the book is a most interesting one, chiefly so, however, in its first pages and their record of the struggles which laid the foundation of the vast practice which was the admiration, and perhaps the envy of his brethren, but of which all must admit the wonder was, all things considered, so much was done and that so well.

ARCHITECTURAL ASSOCIATION.

THE last meeting for the present session of the Association was held on Friday evening, the president, Mr. H. L. Florence, in the chair. Mr. James Lindsell was elected as a member. Mr. HAYES announced that an extra visit had been arranged for Saturday, the 14th inst. (tomorrow), when the President would conduct the members over the new offices of the Holborn District Board of Works at the corner of Clerkenwell and Gray's-inn roads, erected from the designs of his partner, Mr. Isaacs, and himself. The President said he was glad to be able to state that his appeal on behalf of the Architects' Benevolent Society had been well responded to, more than the suggested £100 having been subscribed during the past fortnight. The Presi-

dent further announced that the annual dinner would take place on Monday, the 16th inst., at the Holborn Restaurant.

A TOUR ON THE CONTINENT.

Under this general title Mr. HAMPTON W. PRATT included a paper which he read descriptive of a ramble over about 7,000 miles of country in Italy and France, undertaken during eight months of last and this year. The paper was almost confined to an examination of the modes of church planning in Italy and France. The lecturer struck out the plan of his route as follows:—Starting from Paris he visited Chartres and Orleans, whence he followed the valley of the Loire to Nantes—a district well known, he remarked, for its picturesque chateaux. He next skirted the coast of Brittany, traversed Normandy, and returned to Paris by way of Amiens and Beauvais. Leaving Paris once more, he took a long journey to the south of France, and from thence to Geneva. After a holiday in Switzerland, he went through various towns of North Italy to Venice, and then to Bologna and Ravenna. Crossing the Apennines, Florence, Rome, and Naples were visited, and on the return journey various towns in Lombardy were seen, and he returned by way of Turin and Dijon to Paris. Many of the Italian cities are finely situated on the summits of irregular eminences, but in picturesqueness of buildings themselves, *i.e.*, in outline and grouping, the French are, he considered, far ahead of the Italians, and in some respects, of ourselves. In detail, however, English Mediæval work held the palm for solidity and thoroughness, though the Italian brick, terra-cotta, and stone treatment was refined and pleasing. In a single lecture dealing with such a wide field he must confine himself to one class of buildings, and he proposed, therefore, to deal with the ecclesiastical edifices visited. In Rome and Ravenna were to be found the earliest and best examples of the simple Basilican type of church, with sundry variations. That at S. Cosma e Damiano, Rome, is a nave and apse without aisles. At Ravenna we universally find no transept, but nave, aisles, and an apse, as at S. Giovanni, Evangelista, S. Apollinare Nuovo, and S. Apollinare in Classe. The fine patriarchal basilica of Sta. Maria Maggiore has transepts of same depth as aisles, while at S. Prassede the transepts project beyond. S. Paolo fuori le Mura and the Lateran Church furnish examples of a nave with double aisles, transept, and apse. Unfortunately, all these churches are not spared to us in their original condition—those at Ravenna are perhaps the most intact, while Sta. Maria Maggiore was altered and added to in the 12th, 15th, and 16th centuries; S. Paolo fuori le Mura, once the finest, was destroyed by fire during the present century, and is now rebuilt on its original grand scale, and wears a modern and expensive dress. The Lateran Church has also been destroyed by earthquake and fire, rebuilt and altered at various times. Passing on to consider Mediæval basilican churches, he might mention that it is an exception to find lateral chapels to nave, but these occur at Verona Cathedral, S. Giovanni e Paolo, Venice; S. Petronio, Bologna; Parma Cathedral; S. Croce, Florence; Orvieto Cathedral, and the Certosa di Pavia. The placing a series of eastern chapels to transepts has a very good effect; at S. Giovanni e Paolo, Venice, and at Sta. Anastasia, Verona, there are two to each transept; at the Frari, Venice, three, while Sta. Croce, Florence, has a row of five on either side. Another plan occasionally met with, is a choir raised some 7 or 8 ft. above the level of the nave, and approached by a flight of steps on each side, below being a crypt entered by an arcade from centre of nave, and with a descent of about 4 ft. These Romanesque crypts have often quite a forest of small columns dividing the area into alleys. They are usually used as a winter choir, and are much warmer than the upper part of church, though when crowded as they frequently are with worshippers, the atmosphere is such as to force one to beat a hasty retreat. There are examples of this treatment at San Zenone, Verona, S. Minalto al Monte, Florence, and also at Fiesole, Piacenza, Parma, and Modena Cathedrals. The provision of a triforium gallery is occasionally seen; this arrangement for the accommodation of women occurs in the early basilicas of S. Agnese and S. Lorenzo fuori le Mura, Rome, at a later period in Sant' Ambrogio, Milan, and the Cathedrals of Pisa, Lucca, and Parma. The double-aisled church is not often met with in Italy; besides S. Giovanni in

Laterano and S. Paoli fuori le Mura, may be mentioned Pisa and Milan Cathedrals, both of which have transeptaisles as well, and Pisa double-choir aisles. In the latter cathedral the triforium gallery is continued across the transepts, extending over the two aisles, but reduced to the width of one aisle across the transept. This curious feature does not commend itself to one, for the transepts are already long and narrow between their aisles, and this makes them look more so, moreover destroying the effect of the cross-plan, and suggesting an after filling-in. The transepts of Lucca Cathedral are treated in a somewhat similar way, but instead of the gallery being carried across there is only a wall pierced with similar openings to the triforium and no passage of communication, and, further, the transept itself is divided longitudinally into two aisles by a similar archway and piercings, the effect of which is by no means bad. He next came to a numerous and interesting class of buildings, which left a marked impression on the visitor to Italy; he referred to the numerous churches and baptistries of a round and octagonal plan, and to which a domical covering seems so natural and appropriate. The Pantheon at Rome was, perhaps, the first Pagan temple that was transformed into a Christian church, the consecration taking place A.D. 609, some half-dozen centuries after it is supposed to have been built. Outside the walls of Rome is the circular church of S. Costanza, which is covered with a dome of about 70ft. diameter, and surrounded by a barrel-vaulted aisle opening into the central part by an arcade of 16 circular arches, supported on double columns (one behind the other). This building was erected by Constantine as a monument to his daughter Constantia, and was not converted into a church till 1256. On the Coelins is the interesting church of San Stefano Rotondo, noted for its great size, and originally consisting of a circular space, about 70ft. diameter, surrounded by two aisles, making a total diameter of about 210ft. It was erected at the end of the fifth century, but subsequently fell to ruin, and in the fifteenth century the inclosing wall was formed by filling in the space between the columns dividing the two aisles. At the foot of the Palatine is San Teodoro, another round church, erected probably at the end of the 6th or beginning of the 7th century, and supposed to occupy the site of a temple. Adjoining the Lateran church is the ancient Baptistery of S. Giovanni in Fonte, erected in the 4th or 5th century. The interior consists of an octagon areaded in two heights, covered by an octagonal dome, and surrounded by an aisle. At Ravenna we find Sta. Maria in Cosmedin, a small octagonal-domed building, said to have been an Arian baptistry, the 6th century mosaics being added when it was adapted to the Roman Catholic faith. Adjoining the cathedral is a larger baptistry, also octagonal, and domed; this was erected in the 5th century, and also retains its font of that date. Most interesting of all, however, is the Church of San Vitale, consecrated in 547, and regarded as the earliest Byzantine church in Italy. This singular building consists of a foliated octagon, surmounted by a circular cupola, and surrounded by a regular-sided octagonal aisle, over which is a gallery. Each semi-cylindrical side of inner octagon is pierced with a triple round-arched arcade both at ground floor and gallery levels, and the base of dome is pierced by a two-light window over each recess. The continuity of the aisle and gallery is broken by the formation of a choir, which projects beyond the octagon, and is apsidal-ended. On the opposite side to choir is the principal entrance, now unhappily disused, being rendered inaccessible owing to a large cloister, or parade ground, attached to a barrack. The raising of the whole level of the city of Ravenna has affected this as well as the other churches, the floor being about 3ft. higher than its original level. The effect of the interior is unfortunately spoilt by the painting on the walls and dome in horribly clever chiaroscuro, the colour being in strong contrast with the beautiful mosaics in the choir and the rich marble veneering of the lower part of walls and piers. The Church of S. Lorenzo at Milan is another domed octagonal building; it is surrounded by an aisle, and has four semi-circular apses. At Perugia is the round Church of S. Angelo, supposed to be of the 6th century; the central part is about 40ft. diameter, and has an arcade of 16 circular arches, with a surrounding aisle; the central part is sixteen-sided on the exterior, but no dome exists.

The Baptistery at Florence was formerly the Cathedral. There seems to be some doubt as to the date of its erection, some ascribing it to the 7th or 8th century; its present character is the work of subsequent periods and its present use dates from the 12th century. It is a large octagonal building with a square recess on one side; a narrow gallery surrounds the interior, and at the summit of the cupola is a small lantern erected in the 16th century, before which time it is said to have been lighted like the Pantheon—an arrangement which would be appreciated at the present day by those who wish to see the beautiful mosaics on the dome, but who are deprived of that pleasure except on the very brightest days. S. Sepolchro, Bologna, is probably of the 9th or 10th century. The central part is 12-sided, and covered with a dome of corresponding shape; a 12-arched arcade opens into the surrounding aisle, the outer wall of which is octagonal. This church forms a part of what is considered one of the curiosities of Bologna, namely, a cluster of seven churches all united together, built at different times, and occupying different levels. A rough ground-plan (exhibited) shows that church No. 1 is a late and uninteresting building, from which No. 2 (S. Sepolchro) is entered by a descent of a few steps. This building just described was probably the baptistry to No. 3, which is an interesting brick church of about the same date, and dedicated to SS. Pietro e Paolo. Doorways on the east of the baptistry lead to a sort of atrium which forms No. 4, while a flight of steps in one angle leads to an 11th century crypt under the east end of No. 1, this crypt forming Church No. 5. No. 6 is entered both from the atrium and crypt and is formed by inclosing the north and west sides of an 11th century cloister belonging to a supposed monastery, while No. 7 is an irregular-shaped church of various dates. The seven-fold mystery is thus seen on investigation to be rather far-fetched. The Baptistery at Pisa was commenced in 1153, but long remained unfinished, and was only completed in the 14th century. It is circular on plan, and about 100ft. in diameter, within this circumference being an aisle all round, with a gallery over and an arcade of twelve arches to both stories. The upper part of the wall on exterior becomes a polygon of twelve sides. Covering the whole is a double twelve-sided dome, the inner one conical and the outer one hemispherical. An unpleasant outline results from the cone rising upwards of 30ft. above the outer dome. In the same city is the small church of S. Sepolchro, commenced in the same year as the baptistry, and by the same architect—Diotisalvi; it is an octagonal building, also containing an aisle, and was built for the Knights Templars. The Baptistery at Padua dates from the 12th century, and is interesting on account of its unusual plan, which is a square, surmounted by a circular dome, on the east side being a small apse, also domed; 14th century frescoes cover the walls and dome, and make a delightful interior. At Cremona there is an octagonal domed baptistry, erected towards the close of the 12th century and at the beginning of the 13th century the baptistry at Parma was built; the exterior is octagonal, and the interior sixteen-sided, with two galleries carried round and covered with a dome. The latest of this series of baptistries was the one at Pistoja, erected in the 14th century and built in the characteristic Pisan style, but possessing a very bald interior; it is octagonal and has a lantern at summit of cupola, and also has an external pulpit. We must now consider domed churches, and first will consider S. Mark's, Venice, commenced at the close of the 10th century. Its plan of a Greek cross covered with five cupolas is familiar to all. This arrangement alone is sufficient to interest and delight one, but when to that is added a marvellous wealth of colour on walls, vault, and pavement, our enthusiasm knows no bounds. Of all buildings that have ever been described and analysed, perhaps none have been more thoroughly and lovingly so than S. Mark's, by our architectural poet Mr. Ruskin, and indeed so far has his zeal carried him that he seems to find nothing throughout but what is beautiful and consistent, though others are not prepared to go with him to that extent. Somewhat analogous to S. Mark's, though with no real resemblance, is the Church of Sant' Antonio, Padua, erected in the 13th century. It consists of nave and aisles, transepts and apsidal choir, surrounded by an aisle and chapels, the whole covered by seven cupolas. In spite, however, of this grand con-

ception, the interior suffers from poverty of treatment, while the exterior at first sight has an uncomfortably crowded look. Viewed at a little distance the group assumes a more pleasing form, and the several domes surrounding the more pronounced central one, together with the lofty and slender octagonal minarets, constitute a unique and striking whole. The dome forms also a prominent feature at the Duomo, Florence, Siena Cathedral, S. Peter, Rome, &c. Just a word about the plans of these buildings. That of Sta. Maria del fiore, Florence, consists of an immense octagon 138ft. 6in. internal diameter, surmounted by a lofty dome of corresponding plan. On the north, south, and east sides are semi-octagonal-ended arms, each surrounded by five chapels, and west of the octagon is a long nave and aisles divided into four enormous groined bays. Siena Cathedral has an unequal-sided hexagon at crossing, and a squinch at each angle converts this into a 12-sided figure, covered by a circular dome; this, as at Florence, is crowned by a small lantern. At the crossing of Pisa Cathedral is an elliptical dome which cannot be regarded as satisfactory either internally or externally. The dome of St. Peter is known the wide world over, but the regret may be expressed that so important and striking feature of the interior should be incapable of being seen except at an unreasonable distance. We must next notice the Renaissance churches, erected in large numbers during the 15th and 16th centuries. The grand schemes adopted for many of these churches is a striking feature, and the use of domical coverings a rule scarcely departed from. In Florence is the Church of Santo Spirito, erected from the designs of the architect of the Duomo, although not built till after his death. A somewhat unusual plan is here adopted—viz., a Latin cross, with aisles and semi-circular chapels all round, and a circular dome at the crossing. Sta. Maria Formosa at Venice is a church with barrel-vaulted nave and transepts, domical aisles and three apses. At Ferrara are a couple of churches with some pretence to notice, viz., San Francesco and San Benedetto. The former has domical-covered nave-aisles and transepts, square side chapels, and an apse with two chapels on either side. San Benedetto has a nave and apsidal transepts, domical-covered aisles and apsidal side chapels, three eastern apses, a domed lantern at crossing; the nave, except for a flat cupola, and transepts being barrel-vaulted. The church of San Sisto, Piacenza, has a very effective plan, consisting of a barrel-vaulted nave, transepts, and choir, with dome at crossing; transept also at west end, with intersecting dome, and at end of each of these transepts a chapel. The Church of SS. Annunziata, Florence, is rendered imposing by the large rotunda added to the church by Leone Battista Alberti; this is surrounded by apsidal chapels, and crowned with a frescoed dome. It is much to be regretted that, owing to the lowness of the arch into nave, the dome loses a great deal of its internal effect, as it cannot be seen unless from quite near the rotunda. Pavia Cathedral is said to have been designed by Bramante; the fine central octagon is, however, incomplete; there is an apsidal choir and aisles, but only two bays of nave are built. To Bramante is also attributed the erection of Sta. Maria della Campagna, at Piacenza, a church having an effective plan, based on a Greek cross; the arms are square-ended and barrel-vaulted, a domed lantern covers the centre, and smaller lanterns the corner chapels. Sta. Maria dell' Umiltà, at Pistoja, is the work of a pupil of Bramante, but the master is credited with the design. It is a large octagonal building, covered with a dome, and is preceded by a large and effective barrel-vaulted vestibule, having a cupola in the centre. The Madonna della Steccata at Parma is after the model of St. Peter, Rome, a Greek cross with apsidal-ended arms, a domed lantern in centre, and domed octagonal chapels at angles. Sta. Giustina, Padua, the work of Andrea Briosco, is planned on a grand scale, there being eight cupolas besides the three domical vaults over nave. It has nave and aisles, with lateral chapels, the transepts and choir each terminating in three apses. The exterior of this, as well as so many other extensive churches, presents a dolefully bare appearance, owing to its incompleteness. Sta. Maria in Carignano, Genoa, commenced in 1555, is another church based on Bramante's original design for S. Peter, and occupies a commanding height above the sea, a

site worthy of a better exterior. Of the many works of Palladio, the churches of San Giorgio Maggiore, and the Redentore at Venice are perhaps the best known, the former on account of its prominent position on an island all to itself on the Grand Canal; the cruciform plan, with apsidal transepts and choir and central dome, make a good interior, though it sadly lacks colour. The Redentore has no aisles, but a barrel-vaulted nave, with apsidal-sided flanking chapels, and terminating in a large domed square with eanted angles and apsidal-ended domes. Another prominent church in Venice is Sta. Maria della Salute, erected in the middle of the 17th century, and consisting of a large domed octagon surrounded by an aisle with chapels, on the last of which is a domed square with an apse on each side. In the 17th and 18th centuries we see in Rome, Modena, and elsewhere, several instances of churches constructed in the circular, octagonal, and elliptical forms, as well as on the Greek cross, while Turin and Naples have each an example of a church built at the beginning of this century on the model of the Pantheon. These Renaissance churches possess some interest in their planning, if their architecture is not such as all admire, and the author confessed that the cleverness and ingenuity often displayed in some of these buildings frequently overcame his prejudices. Before leaving the subject of Italian churches he would refer to some exotics. The famous Church of San Francesco, Assisi, erected in the 13th century, was the work of the German architect Jacopo, and exhibits a decided Northern character, while Milan Cathedral, of the 14th century, is said to be the work also of a German, or of an Italian architect trained in Germany—certainly, it bears little resemblance to Italian work, whether in plan, proportion, or detail. Geneva Cathedral, in some respects, has an affinity to French work, and the 13th century Church of Sant' Andrea, Verceili, with its square-ended choir and buttresses, is supposed, with good reason, to be the work of an Englishman, though Mr. Street considers that the exterior shows no trace of any but an Italian hand. There is no example of the French chevet in Italy, the nearest approach being the choir of Sant' Antonio, Padua.

(To be continued.)

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE last ordinary meeting of the Institute for the present session took place on Monday evening, the President, Mr. John Whicheard, in the chair. The following gentlemen were balloted for and elected to membership:—As Fellows: Laey William Ridge (associate), Bedford-row, W.C.; Charles Baker (associate), Leicester; Isaac Barradale, Leicester; Henry Shenton, Leicester; Hugh Rounieu Gough, Queen Anne's-gate, S.W.; Campbell Douglas (President of the Glasgow Institute of Architects), St. Vincent-street, Glasgow; and Alexander Graham, Carlton Chambers, Regent-street, S.W. As Associates: Walter Alfred Dugleby, Napier, Hawkes Bay, New Zealand; Thomas Garratt, Shepherd's Bush; and William Owen, Deansgate, Manchester. As Honorary Associates: Capt. Thomas Bridges Heathorne, R.A., Wilton-place, Knightsbridge, S.W.; John B. Monckton, F.S.A., Guildhall, E.C.; Rev. Canon Edmund Venables, M.A., The Precentory, Lincoln; Rt. Hon. Sir William Robert Seymour Vesey Fitzgerald, G.C.S.I., Charity Commissioner, Warwick-square, S.W. The SECRETARY having read a list of donations to the library, Professor DONALDSON called attention to one of these, the "Life of Mr. J. B. Papworth," remarking that it was a biography of a valued friend of his. To a genial manner and a kind heart was added in Mr. Papworth a lively genius and practicable skill. He was one of the founders of the Institute, and devoted much attention to the preparation of the rules.

THE LATE PROFESSOR SEMPER.

The SECRETARY announced the deaths of Mr. Edward Brainerd Webb, F.G.S., M.I.C.E., an hon. associate; Mr. Horace Field, associate; and Herr Semper, honorary and corresponding member.

Professor DONALDSON read a short and appreciative memoir of the last-named member.

Gottfried Semper, whose death at Rome had just been announced, was, he said, an old and valued friend of his; for him he entertained a sincere personal regard, and for his talents a genuine admiration. The earliest notice of him was in an essay on Greek architecture, by Kübler, which appeared in the first volume of "Instituto Transactions," in 1836, in which reference was made to Herr Semper having traced a complete scheme of colour-decoration on all the Greek remains of the age of Pericles, and to his conjectural restoration of the temples, which was at that time regarded as very ingenious. Semper was born at Altona in 1803; he first studied law in the University of Göttingen, and then turned his attention to architecture, subsequently pursuing his studies at Munich and at Paris. He afterwards visited Italy and Greece. In 1831 he published his first essay on architectural subjects, and in the same year was appointed Professor of Architecture in the University of Dresden, on the recommendation of Schinkel. About 1841 he prepared plans for the new theatre in that city, which was burned down in 1869—a work in the Italian style, which was noticeable from the refined and pure taste with which the plan was carried out in all its details. He executed much work in the city, and in 1847 began the new museum there. He was appointed architect to the King of Saxony, but in 1849 he allowed his irrepressible love of liberty to so far overrule his better judgment as to take part with the insurgents, and it was charged against him that he actually prepared plans of Dresden showing where the barricades should be erected. He was obliged to leave the city, and this was the commencement of a long series of years of misfortune. He went to Paris and afterwards came over to England in order to find security, and in search of possible employment. In 1852 he obtained an appointment in the Department of Practical Art at South Kensington, and delivered lectures on the decoration in colour of materials of every kind. In 1853 he made sketches for covering the site of South Kensington Museum with buildings, for which he was paid by the Prince Consort. He also designed the art certificate of the Department. After spending a few years in this country with his family, he was at length offered and accepted the post of Professor of Architecture in the University at Zurich. In the city he carried out many important works, including numerous buildings in the Upper-town, the Polytechnic School, and especially the very fine railway station. In this last building, the internal halls are conceived in the style of the thermæ of the Romans, and the decorative features are admirable. In 1866 Semper represented Switzerland, as Commissioner, at the International Exhibition at Paris. He designed the Swiss buildings in the exhibition, and took the opportunity of carrying out his theory of decoration by colouring them a bright red. In 1871 he was commissioned to rebuild his theatre at Dresden, destroyed by fire two years previously, but the principal work was practically carried out by his son. In 1869 he had made designs for a new exchange at Vienna, and in 1870 he was called upon to select a design in the competition for a new museum in Vienna, and eventually carried out the building in conjunction with the architect whose design he recommended. He settled in Vienna, and erected many important buildings there, including material additions to the Imperial residence. His closing years were not happy, as he was afflicted with asthma; he spent his time alternately in Venice and Rome, and died in the latter city on the 15th May, in the 77th year of his age.

Mr. WYATT remarked that Mr. Brainerd Webb, whose decease had also been announced, was for many years a civil engineer practising in Dublin; he was formerly the engineer of the Dublin and Coleraine Railway. He joined the Institute as an Hon. Associate last year. On the motion of Messrs. Barry and Wyatt, a cordial vote of thanks was accorded to Professor Donaldson for his paper.

THE RECENT EXCAVATIONS OF THE ROMAN FORUM.

Mr. EDWARD L'ANSON read a paper on this subject, which is reproduced on page 673.

After the reading of the paper, Professor Donaldson, and Messrs. E. C. Robins and C. Forster Hayward expressed their concurrence in the views expressed. In reply to questions, Mr. L'ANSON traced on the map the excavations now being carried on at the east side and south end of

the Forum at the cost of the Italian Government, under the direction of Cavaliere Rossi, who is preparing an elaborate work on the Forum. He also mentioned the very thorough manner in which Mr. John Henry Parker is carrying on his investigations, at very considerable personal expense, but said he could not agree with the conclusions of the latter author. A cordial vote of thanks for his paper was passed to Mr. L'ANSON, at the suggestion of the President.

THE ARCHITECTURAL ASSOCIATION AT ST. ALBAN'S ABBEY.

THE members of the Architectural Association paid a visit to St. Alban's Abbey on Saturday afternoon. Several accidental circumstances—the absence from the city of Mr. Scott, as well as of Mr. John Chapple, the clerk of works, who had been expected to conduct the party, a special service arranged for five p.m. in the central portion of the abbey, and not least the heavy and persistent rainfall of the latter part of the day—contributed to deprive the excursion of some anticipated pleasures, but the fifty or sixty members present made good use of the three hours they spent in the abbey. The President-elect, Mr. S. Flint Clarkson, according to a general request from the members, undertook at short notice the duties of *cicerone*, and in his peripatetic lectures evidenced an intimate acquaintance with the history and features of the abbey, and advanced independent theories as to the dates and causes of the numerous alterations in plan and design, which render the youngest and longest of our cathedrals so deeply interesting an architectural patchwork. Starting in the western portion of the nave, now partitioned off and used as a workshop and storehouse during the erection of the new roof, Mr. Clarkson expressed his opinion that the Norman Abbey of Paul de Caen, consecrated in 1115, was shorter by the four western bays than the present building, but that the present deep and wide transepts were original. At the east end it probably terminated in an apse, and at the west end in three apses. It had been supposed that the massive, unpierced south wall of the western bays of nave was of Norman origin, but he could see no evidence for or against this in the masonry. He then traced step by step the progress of the work; the Early English bays of John de Cella, Trumpington's alterations, the catastrophe of 1230, when the eastern arm of church fell, the rebuilding and extension of the Lady chapel, the reconstruction of portions of the south side of nave in the Decorated period, but on the Norman proportions, the insertion of later windows and other alterations. The mode in which successive generations of builders altered older work to suit their own ideas, and cut down the carvings and mouldings when pressed for means, was pointed out in a clear manner. Proceeding to the eastern extension of choir, Mr. Clarkson showed how curiously the 13th Century builders dealt with the difficulty of forming three deeply splayed openings from the choir into the Lady chapel within the width of the central span of the church without interpenetration of the mouldings at the angles or sacrifice of space. The way in which the mouldings of these arches were managed was awkward and complicated and anything but satisfactory, and compared disadvantageously with the treatment of a similar problem on the north side of ante-chapel, where the lines of the members are permitted to cross each other. In the retro-choir, the angle wall shafts spring from twisted corbels of unique form. The principal hollows of the mouldings of these arches are stopped by a chamfer block of enriched character, a not unusual expedient in early work, and thus the unsightly setting back of the arch immediately over the cap is avoided. In this retro-choir the arches of the triforium are out of proportion to the slender columns, and the very large roll of the shafts scarcely harmonises with the caps and bases. It was evidently intended to vault this portion of the building in stone; the shafts and springers were carried up, but the whole was subsequently finished in wood, with very little injury to the architectural effect. The history of the finding of the 2,000 fragments of St. Alban's shrine, built into a temporary wall between the retro-choir and ante-chapel, and its reconstruction by Sir Gilbert Scott, was narrated, Mr. Clarkson observing that

the Mediæval artist who designed this reliquary did not hesitate to colour the church tracery to harmonise with the Purbeck marble shafts. Passing into the Lady chapel, for the past three centuries used as a grammar school, but now in course of restoration, the exquisite character of the Early 11th Century architecture of the upper portion was pointed out. It was shown that the portion below the window-sills was almost half a century earlier in character. The windows, which of course belonged to the later work, are of great elegance and refinement. On the jambs are unique carved figures, set at regular intervals, with traces of diaper and scroll colouring above. The mullions are gradually reduced in thickness to the head, so that the transition to the thin pieces of tracery is very gradual; this *finesse*, which only came into vogue when contraflexure was adopted, is not observed in the otherwise graceful south-east window of the ante-chapel, the consequence being that the cusped circle of tracery seems to be a subsequent insertion. Some discussion took place as to the date of the central window on the south side of the Lady chapel, Mr. Page suggesting that it was a Perpendicular insertion, while others thought that all but the central tracery of the head was 14th century. Returning to the ante-chapel, the rich and greatly mutilated arcading on the south side and eastern return was admired, general regret being expressed when it was stated that the Restoration Committee propose to renew it in the spick-and-span, mechanically correct style of the north side if funds can be obtained for the purpose. In the north aisle of choir a halt was made opposite Abbot Ramryge's tomb, which forms a chantry chapel. Mr. Clarkson showed how the solid wall was cut away in the 15th century in order to insert this immense screen of stone tracery, with the result of endangering the safety of the tower. The abbot's rebus, a ram leaping, was incessantly repeated throughout the design, while, quaintly enough, every cusp in the tracery was incurved into the peculiar twist of a ram's horn, and, said Mr. Clarkson, one could imagine the chuckle with which the designer must have witnessed the carving and setting up of each successive volute in this gigantic pun. We cannot follow Mr. Clarkson in this matter of the cusping. Opposite this, on the outer aisle wall, was the delicate 13th Century arcade of which a recent lecturer at the Association (Mr. James Neale, F.S.A.) had stated he had collected and collated seven or eight drawings, all of which differed from each other. The explanation, said Mr. Clarkson, was simple: the arcade was uniform in scale, but the lines and drawings of the columns and arches were not uniform either in design or execution. As a consequence no two bays were precisely similar, but the various draughtsmen, after having measured one bay, have failed to observe this variation, and have made the others uniform with the one copied. Entering the choir, the mode in which the heavy Norman work had been lightened by subsequent architects, though they dare not cut through the masonry lest the tower should be imperilled, was indicated. The 13th century architects cut-back arcades on the face of the walls, and to get more play, omitted the cap of the main shafts, while giving fully developed eaps and bases to the return shafts on either side. Panelling was added by later architects with the same aim. The 15th Century panelled altar screen is a very fine one, and so nearly resembles that at Winchester that they have been erroneously supposed to be replicas. Returning to the south transept, the ingenious mode in which William de Trumpington strove to remedy its darkness by piercing new windows above the level of the adjacent cloisters, and, therefore, above the triforium, was pointed out, Mr. Clarkson showing that where the eills of these splayed lights impinged on the triforium a new and shorter column with modified cap had to be designed and placed in the row of balusters. The party then went to the central western porch, the extreme beauty of the Early English mouldings in this being referred to; Sir Gilbert Scott had, indeed, declared this work to be unequalled for grace and elegance in any portal of the period, and only approximated to in the Galilee at Ely. The mode in which William de Trumpington, in completing John de Cella's work in this porch, cut down and modified the design gave rise to a little discussion as to the relative merits of the two schemes, the general opinion being in favour of the older work. It

was shown that the masonry which Trumpington found already prepared were used, as far as it went, in accordance with the new ideas, but with less elaboration of parts, the Purbeck shafts being simply omitted. The other porches were also looked into, it being demonstrated that the triplet of portals could never have been intended to intercommunicate, as Sir G. Scott thought before opening up the ones on the north and south, as the flanking lines did not meet. The foundations of the tower once proposed on the south-west side having been examined, Mr. Clarkson said that Sir Edmund Beckett had proposed to pierce this south aisle wall, now solid, with windows. It was admitted that no windows could have been opened here in pre-Reformation days, because the monastic buildings abutted on this portion of the abbey; but Sir Edmund held that if Mediæval builders had seen them removed they would not have scrupled to open out lights. Mr. Clarkson suggested that any if one candidly supposed that this portion of the church, faced as it was by the immense west window, and having north aisle and north and south clerestory lights, was insufficiently lighted, he must be difficult to convince. The re-roofing of this western portion of the nave, it was seen, was actively progressing. Piles of deal worked into principals bestrew the central area, and there are also stacked near the entrance some hundreds of leaden pigs for the covering in, which it was stated it has been decided shall be of lead. Some of the painted wooden panels temporarily removed from the ceiling were examined; they are of 3 oak, coarsely painted by hand with conventional scroll patterns, and a lion *passant* or *regardant* at the four corners of each device. This boarding is generally in a good state of preservation, but it is fragmentary, and the mode of storage during the alterations does not err on the side of vigilance. Heedless of the heavy shower, the members went outside the Abbey, while Mr. Clarkson stated the case for and against the raising of the pitch of the roof, showing that the advocates of the high-pitched roof based their plea to some extent on the grooves still apparent on the brickwork of the west face of the tower, while the other party had declared that these were merely masons' lines, and that Roman tiling unscored and apparently of the original bonding-in intercepted these grooves. Mr. Clarkson was pressed as to his view of the controversy, but this he declined to state, saying the facts as well as the arguments were before the members' eyes. Many of the principals have already been raised to the roof, but none are as yet set up. In walking round the Abbey satisfaction was expressed that the old pathway through the Lady Chapel had been diverted to the east of the building. It was found impossible, owing to the incessant rain, to complete the external survey, but before separating a hearty vote of thanks was passed, on the motion of Mr. Blashill, to Mr. Clarkson for the genial and instructive manner in which he had discharged the rôle of guide, philosopher, and friend.

Amongst the numerous illustrations of St. Alban's Abbey, which have appeared in recent volumes of the *BUILDING NEWS*, we enumerate the following as those of chief interest:—General plans of monastic buildings, Feb. 25, 1870, and Feb. 8, 1878; another of the Abbey and adjacent buildings to large scale, June 21, 1872; perspective views of Abbey from S.W., Feb. 18, 1870 (Sketchbook Series, No. 19); and from S.E., Sept. 22, 1871, and May 21, 1878; bays, north side, nave, May 17, 1878; central west porch, Sept. 16, 1870 (Sketchbook Series, No. 43); carvings in N.W. porch, &c., Dec. 28, 1877; an interior doorway, July 22, 1870 (Sketchbook Series, No. 37); Duke Humphries' tomb, Feb. 23, 1877; the slype, Feb. 23, 1877; and sections of old and new roofs of nave, Dec. 6, 1878, and Jan. 3, 1879.

CHAPEL ARCHITECTS.

ARE-PERUSAL of Mr. Cubitt's well known book, "Church Designs for Congregations," has led the editor of the *Freeman*, the leading Baptist organ, to give the following fancy sketch of the way in which Dissenting chapels are sometimes built:—

"First, a committee is appointed, chiefly of men wholly unacquainted with the work before them. Contributions come in well. The power of the voluntary principle is illustrated. The

committee meet and talk over what is before them. There is no disagreement as to what they require, but very little agreement as to how it can be secured. Deacon A., who has never done such a thing before, sketches a plan in pencil. It is an oblong building, fifteen feet by forty-five feet; he thinks it would seat about 900 on the ground floor, and that side galleries could afterwards be added. Brother B. has sat up all night with some red and black paint, and produces a cruciform building like a cathedral, with two rows of piers shutting out the view of the pulpit from numbers; he altogether overlooks the need of a porch, and places the schoolroom under the chapel, making no provision whatever for lighting it. Another member gets his daughter to draw out a sketch of a Wesleyan village chapel, very pretty, but with the windows overlooking a neighbour's ground, all of which would be blocked up at once. The committee discuss and discuss with considerable development of patience and temper. At length a neighbouring gentleman sends a promise of £10, and strongly recommends a friend of his own who, he says, is a rising and gifted architect, and would undertake the work for half the regular fees. The architect sends for inspection a number of pictures he has drawn, and, being tolerably clever at water-colour drawing, they look well. He is invited to meet the committee. "What kind of a building do you need?" he asks. Says Deacon A., "We want a good, substantial building, with none of what I call frippery; no useless ornamentation, no foolish pinnacles and what not; but a plain, handsome place, that shall be an ornament to the town." "Exactly so," all the others respond. The architect, if feeble in skill, is shrewd enough to measure the meaning. He sees they know nothing about it. For who ever wanted a building that was not good—that was not substantial? Who ever wished for frippery and foolish ornaments? Who would not be delighted to secure a place that should be plain and handsome, cheap, and yet an ornament to the town? So the architect engaged them for half an hour in technical expressions. Very soon they were all out of their depth and overwhelmed with his learning and genius, and he left them promising a design on approval. Within a week the design came. Purposely it had some very obvious defects. The pulpit was six feet two high, and the vestry door very awkwardly placed. The committee were dazzled with the first sight of the well-painted picture. Deacon A. suggested that the pulpit should be lower. Another thought the entrance to the vestry could be altered with advantage. The architect flattered them on their penetration, altered the design, cut off some two pinnacles (which he had never intended to keep on the plan), said that these alterations would diminish the expense by some £500, and the design was accepted and signed. The contract was taken by a builder who saw at once what was to be done. He knew well the measurements would never do; the strength was all in the wrong places. As he went on with the work this became evident enough; had he completed it the roof would assuredly have fallen in. From the time this became apparent, the architect and builder understood one another, and pulled through pleasantly together somehow. The result was a well-built place without any frippery, and most people were satisfied. The porch was Saxon; the side windows were Early English; on the south, opposite to the pulpit, was an immense Perpendicular window, summarily to bring the sermon to an end by blinding the preacher at noonday; the vestry was Tudor, and the gallery was supported by Doric columns; an Italian lantern crowned the whole. As for draughts and acoustic arrangements—well, they were trifles left to take their chance. It was a fact that a noble place, in pure style, could have been built for the same sum of money. Principles of comfort and hearing might have, without extra cost, formed part of the plan. But nothing was contributed to the knowledge or increase of taste in chapel architecture."

The following buildings are now in the course of erection, from the designs and under the direction of Mr. John Hillary, architect and surveyor:—Longparish, Hants: new house for R. Dowling, Esq., at Andover, Hants; Messrs. Annett and Son, builders, Andover; amount of contract, £949 7s. New house for H. Dowling, Esq., at Andover; Messrs. Annett and Son, builders; amount of contract, £1,200. New farmhouse for H. Harris, Esq., at Stevenon, Hants; Mr. G. Batten, builder, Overton, Hants; amount of contract, £900.

NEW VESTRY HALL, BROMLEY.—CABINET DESIGNED FOR MARSH, JONES, AND CRIBB.—ST. GREGORY'S MONASTERY, DOWNSIDE.—HOUSES IN NIGHTINGALE-LANE, WALWORTH.—CITY OF GLASGOW BANK, GLASGOW.—NORFOLK AND NORWICH HOSPITAL.

OUR LITHOGRAPHIC ILLUSTRATIONS.

BROMLEY VESTRY HALL AND PAROCHIAL OFFICES.

The foundation-stone of this building was laid on the 24th May, 1879. It is intended to accommodate the vestry and its officers. The site is in the Bow-road, where formerly stood Mrs. Bowrey's alm-houses, in the parish of Bromley St. Leonard, Middlesex. The frontage of the building is 53ft., and is to be faced with Portland stone. The rooms provided are, on the ground floor, committee-room, rate collector's office, vestry clerk's offices, vestibule, and entrance hall, leading to a stone staircase, which gives access to the vestry hall, which is 48ft. by 32ft., and occupies the whole of the first floor of the front or main portion of the building. In the rear portion of the building are first and second stories, containing a waiting-room, and here are housekeeper's apartments, approached by a separate staircase. In the basement is a fireproof muniment room. The builders are Messrs. J. and H. Cocks, of Mile End, E., whose contract is £5,266. The designs are by Messrs. A. and C. Harston, 15, Leaden-hall-street, E.C.

CABINET FOR MESSRS. MARSH, JONES, AND CRIBB.

This cabinet is to be executed in American walnut, with carved black wood panels, and some of the mouldings relieved with ebony from design and details furnished by Messrs. F. and A. Wheel-don, architects, Birmingham and Wolverhampton.

ST. GREGORY'S CHURCH, MONASTERY, AND COLLEGE, DOWNSIDE.

We publish to-day a bird's-eye view from S.E., together with plan, of the group of monastic buildings erected for the English Benedictines at Downside, near Bath. Messrs. Dunn and Hansom are the architects. The plan of the monastery is an attempt to revive something of the arrangements carried out in mediæval buildings. A perspective of the exterior of the church and the library, taken from the south-east, appeared in the BUILDING NEWS for May 30,

1873, and another of the interior of the church on October 16, 1874. The drawing now reproduced is hung at the present time at the Academy.

HOUSES AT WANDSWORTH.

THESE houses which we illustrate this week from the pen and ink drawing now on view at the Royal Academy Exhibition are being built in Nightingale-lane, Wandsworth, by Mr. Jennings, the sanitary engineer, who is his own builder in this case. The buildings were originally intended to be faced with Tisbury stone, but the detail has been slightly altered from the first design to allow of the work being carried out in red brick and terra-cotta. The terra-cotta is being made by Mr. Jennings at his works at Parkstone, and is of a buff colour. The sanitary arrangements of the houses will be on as perfect a model as can well be conceived, all Mr. Jennings's latest improved apparatus being employed, and the same may be said of the heating of the halls and staircases, as well as the ventilation throughout, all being in the proprietor's own method. Mr. T. E. Collent is the architect.

CITY OF GLASGOW BANK—NEW HEAD OFFICE, GLASGOW.

THE building which forms the subject of the illustration was in course of erection, and nearly completed, at the time the Bank stopped payment in October last. It has since been completed and roofed in at the level of the main cornice, but the work above this stage will not now be done. The material used for the building is from the Overwood Quarries, with a granite base up to the height of the street floor sills. The architects are Messrs. Campbell Douglas and Sellars, Glasgow.

NORFOLK AND NORWICH HOSPITAL.

THIS building, the foundation-stone of which is to be laid by the Prince of Wales on the 17th inst., is now in course of erection. The original Norfolk and Norwich Hospital was built in the year 1771, and for long had the reputation of being one of the best arranged buildings of its kind in the kingdom. Of late years, however, it has been found insufficient in accommodation, and altogether unsuited to the requirements of modern medical science. In 1876 a scheme was set on foot for the enlargement and remodelling of the old building, which at once received the most cordial support of the Prince of Wales and the leading inhabitants of the city and county, and plans were prepared by Mr. E. Boardman, of Norwich, architect to the hospital, showing how these improvements might be effected. As, however, the subscriptions to the "Hospital Restoration Fund" exceeded expectation, and it was found to be impossible to adapt the old building successfully to modern requirements, the governors eventually determined to build an entirely new hospital. The new building is being erected partly on the site of, and partly on the grounds belonging to the old hospital, and is arranged on the separate pavilion principle, connected by corridors, as shown by the ground plan. A portion of the old hospital (on the north-east side of site and nearest to the city) is retained, and is to be rearranged and enlarged so as to contain the out-patients' department, museum, &c., on the ground-floor, together with a nurses' home on the 1st and 2nd floors, communication with the new building being provided by means of a covered way. The pavilions are two-storied buildings, the 1st floor of each being exactly similar in arrangement to the ground-floor, a 2nd floor being formed over the central portion of each, to contain bedrooms for the female servants of the establishment. The central compartments between the large wards, contain the principal staircases (giving access to the upper floors), nurses' rooms, sculleries, &c. The administrative block, which is placed in the centre of the new building, contains on the ground-floor, board-room, library, surgery, large waiting-hall, &c.; on the 1st floor, resident medical officers' sitting and bedrooms; and on the 2nd floor, bedrooms for pupils and men-servants. The kitchens, servants' offices, and store-rooms are placed in the basement of this block, round which are large areas and open spaces giving abundant light and ventilation to the basement story. Behind the administrative block is placed the Operating department, effectually separated from the noise and traffic of the rest of the hospital; it contains a spacious operating theatre, with

several small wards arranged round it for special surgical cases. The chapel, which will accommodate about 110 persons, is placed at the N.E. corner of the site, and is connected with the main building by a vestibule. The new building is being executed in local red bricks, Cossey bricks being used for the moulded and ornamental portions, with stone dressings sparingly introduced, the roofs being covered with Broseley tiles. All the internal woodwork is to be of pitch-pine varnished, and the fittings throughout will be of the best and most approved description. The chapel, corridors, staircases, waiting-rooms, &c., are to be heated by hot-water coils, the large wards being heated by Mr. H. Saxon Snell's patent "therm-hydric stoves," and the small wards by means of open fireplaces. The ventilation will be effected by means of extracting flues in the ceilings of the different rooms, connected with large exhaust shafts in the roofs (heat being the extracting power), to remove the vitiated air, fresh air being introduced through gratings at the floor level. Great attention has been paid to the sanitary arrangements throughout the building. The height, from floor to ceiling, of all the wards and principal rooms throughout will be at least 14ft., that of secondary rooms varying from 9 to 12ft. The total number of beds provided for in-patients is 200; accommodation is provided for 8 medical officers and pupils, 30 nurses, and 10 domestic servants, together with matron, housekeeper, and secretary. The minimum cubic space per bed allowed for ordinary wards is 1,500 cubic feet, and for surgical wards 1,900 cubic feet. The cost of the building, including chapel and the alterations to portion of old hospital, may be taken at £46,000, of which sum about £36,000 has been already subscribed or promised. At present only a portion of the building, comprising the S.W. pavilion with the administrative and operating blocks, is being erected, the principal portion of the old hospital being retained for use until this part of the new building is ready for the reception of patients, by which time the committee hope to have received sufficient subscriptions to enable them to carry out the whole scheme. The works are being executed by Messrs. J. and W. Lacey, builders, Norwich, the designs having been prepared by Mr. Thos. H. Wyatt, of 77, Great Russell-street, London, and Mr. E. Boardman, of Queen-street, Norwich, joint architects.

CHIPS.

A new lecture-hall and schools in connection with the Congregational Church, Highfield Park, Rock Ferry, were opened on Thursday week. The new building has been erected on the south-west side of the church, and is in harmony with it, both having been built from designs by Mr. D. Walker, architect, Liverpool. The large lecture-hall, on the second floor, is 67 feet in length by 32 feet wide, and will seat 500 people. The ground-floor is divided into several school and class-rooms. The building is of Storeton stone, the dressings being of the same material. The works have been executed to Mr. Walker's plans by the contractor, Mr. James Bratt, of Rock Ferry, and the cost will be about £2,000.

A very unusual scene has just been witnessed in the village of Shapwick, Dorsetshire. The parish church has long been out of repair, and steps have been in progress for some time to raise funds to restore it; but difficulty has been experienced in getting sufficient money for the purpose. With a view of partially surmounting the financial obstacle, it was proposed and agreed that the unskilled labour in connection with the restoration should be done by the able-bodied men of the parish. Consequently, one evening last week all the Shapwick men, under the leadership of the vicar and the superintendence of the architect, assembled to perform their part, and they worked with such eagerness that at dusk everything had been done to prepare the building for the incoming of the restorers: all traces of gallery and pews had been destroyed, the flooring and paving stones carried out of the church, and the whole edifice reduced to the necessary skeleton-like condition.

The church of St. Mary, Mariansleigh, near South Molton, was reopened on the 30th ult., after restoration. Mr. W. C. Oliver, of Barnstaple, was the architect, and Mr. John Cock, of South Molton, the builder.

At the Putney Board of Works, on Wednesday week, it was unanimously resolved to increase the salary of the surveyor, Mr. J. C. Radford, £50 a year. The question was brought forward by Mr. Collier and Mr. Cutler, who spoke in high terms of Mr. Radford's energy and ability.

THE RECENT EXCAVATIONS OF THE
ROMAN FORUM.*

ALTHOUGH the subject of the Roman Forum has been more than once discussed in this room, still it is a subject ever replete with interest, and as the excavations which have been going on during late years have disclosed facts and settled questions which have been matters of voluminous controversy amongst antiquarians and literary men for generations, having recently seen these excavations, I now propose to describe their present condition. I am neither an antiquarian, or versed in classic lore, so that all I purpose to do is to record what I observed, and to note the conclusions which others have drawn from the facts disclosed. When I first visited Rome my knowledge of the classic monuments it contained was derived from Taylor and Creasy's book, two interesting folio volumes, and such information as Mrs. Starke's Guidebook afforded, for it was before either the days of Murray's Handbook, or the learned observations in Bedeker's Handbook, that I paid my first visit. At that time the Roman Forum was a plain extending from the base of the Capitol to the Colosseum, and the monuments then visible consisted of the upper portions of two groups of columns known as the remains of the Temple of Jupiter Stator, now determined to be the Temple of Castor and Pollux, one group of Ionic columns, a considerable part of the podium on which they stand, and one single column which had been excavated to the base by the Duchess of Devonshire in 1813, and which in Byron's time was called the nameless column with a buried base. Besides these there was the triumphal arch of Septimius Severus at the north-west end of the forum, and this was all. I will now endeavour to describe to you the Forum as I saw it last November and December. I propose to follow the description, and in many cases the words, of the latest English work I can find written on the subject (Nicholls' Roman Forum), published by Longmans in 1877. Beginning, then, at the north-west end of the forum, we find a large building constructed on the south-eastern slope of the Capitoline Hill; much of the lower part of the building remains, it has been raised upon by Michael Angelo, and is now incorporated with the senatorial palace, of which the principal façade is in the Piazza del Campidoglio. The façade which is next the forum is very lofty, and forms a conspicuous object, constituting a considerable part of its north-western boundary. In this building was a long arcade, one half of which is now open with Doric half columns at the sides, and the capitals of several other columns; any considerable traces of the corrie indicating the continuation of the arcade may be seen embedded in the walls by an inscription which existed until the 17th century. This building is known to be the Tabularium or Public Record Office. Its destruction by fire is twice alluded to by Cicero; it was rebuilt by Quintus Lutatius Catullus, Consul, B.C. 78; some portions, however, must be of more ancient date, being built of tufa. The lower and ancient part, which is now used as a museum for the reception of the architectural gleanings arising from the excavation of the forum, is still in excellent preservation, although a portion used during the middle ages as a storage for salt has been much injured by its corroding action on the tufastone. Above the ancient part is reared the lofty buildings added by Michael Angelo. On the south-west side of the Tabularium is the principal road leading from the capitol to the forum called the Clivus Capitolinus. On the north-east side of the forum, under and against the Tabularium, are the remains of the Temple of Concord, the extensive podium of which, with its rich marble pavement, and some portion of the outer walls with its marble lining and plinth, still remain, particularly next the western angle. The building of which we see the remains appears to have consisted of a large cella placed against the wall of the Tabularium, with a portico of less width projecting towards the forum, the portico being approached by a lofty flight of steps, but none of the columns are left remaining. Between the cella and the portico are two wide marble cills, on one of which the door was placed, and on the cill of one—the mortices for the hinges or pivots on which the door hung are observable—is a shallow sinking in which the figure of a caduceus, probably of bronze, appears to have been imbedded.

When Varro wrote there seems to have been not only a Temple of Concord but a basilica called the Basilica Opimia on this ground, and in earlier times in the same locality a building called the Scaeculum also stood. Some antiquarians, I believe, now consider that this ruin did consist of two separate buildings. The first Temple of Concord placed on part of this site was probably that of M. Fricenes Camillus, B.C. 367. The temple existing in the time of Cicero and Varro appears to have been erected in the forum by L. Opimius, Consul B.C. 121. The edifice of which we see the present remains was, it is believed, undertaken by Tiberius during the reign of Augustus, A.D. 6, and dedicated after the triumphal return of Tiberius from his German campaign, A.D. 12. This temple was frequently used for the meeting of the Senate; it was to this place Cicero brought the accomplices of Catiline, and here he exposed the conspiracy, whilst the Clivus Capitolinus was thronged with the noblest of Rome. It was here that Caesar was threatened by the Roman knights, and it was here that after Caesar's death Cicero and the Senate defied Mark Antony. The base of the temple at the southern extremity is composed of rubble masonry, then follows a rubble wall, and at a still higher level is a mass of stone rubble work, forming no doubt the substructure of the steps leading from the level of the Forum up to the floor of the temple. Where the cella appears to join the portico are two large massive stones which apparently formed the cill of the door or doorways either of the cella or of two separate buildings. On the northernmost of the two cills are two deeply recessed mortice holes as though to receive the pivots or studs on which the door turned, and on the other cill is the matrix of what appears to have been a figure of the Caduceus, probably in bronze. The cella of the temple (or if it were so, the separate building next the Tabularium) is covered with marble paving, but the whole is much fractured. The back wall does not touch the wall of the Tabularium, but there is a small space between the two buildings. There are considerable traces of the marble lining of the walls at the south-west corner, and there are also ruins of a brick construction, the remains of a church of the middle ages built within the area of the ancient temple. On the wall of the Tabularium, at the back, or close to the back, of this temple, is an excavation through an ancient doorway, made, as I understand, at the expense of our veteran English archaeologist, Mr. Parker, to ascertain whether it formerly communicated with the interior of the Tabularium; but the excavation does not lead to this conclusion. In front of the ruin of the Temple of Concord stands the arch, which its inscription shows to have been erected in honour of the Emperor Septimius Severus and his sons Caracalla and Geta, but from which the name of the last was erased by order of Caracalla. The carriage way between the Temple of Concord and the north-west front of the arch of Septimius Severus is part of the ancient road leading from the Clivus Capitolinus to the prison, but the road branching from it and passing under the arch is probably not older, if indeed so old, as the arch itself. The Via Sacra runs steeply up to the arch of Septimius Severus, and just within the modern roadway is a large altar base and a square altar. The north side of the arch is very ruinous, and there are several mortice holes for the insertion of timber, but the south side of the arch is in much better preservation. The central roadway through the arch is paved; after passing through it turns sharply to the south-west, and the paving is very dilapidated; the footways through the arch are paved with square stones not very regularly laid. Beyond, and north-eastward of the arch are some remains, which are supposed to be those of the equestrian statue of Marcus Aurelius, now in the Piazza del Campidoglio, certainly one of the finest, if not the very finest, equestrian statues in the world. At the western corner of the arch in front of the Temple of Concord is the nucleus of a tall, circular structure about 15ft. in diameter, supposed to be the Umbelicus Romæ. Commencing from the Umbelicus Romæ is a platform on a level, or nearly so, with the ground next the Capitol, with a perpendicular face about 10ft. high, forming part of a circle towards the forum which is cased with marble, and on which there are several projections and the remains of copper cramps, to which some antiquarians, and amongst others Canina, considered the rostra of vessels were affixed. Part of this monument is still covered by the modern

road carried on a higher level by arches, and which here traverses the forum in a south-westerly direction. Returning to the wall of the Tabularium we find separated from the Temple of Concord by a passage of about 5ft. in width, the remains of a temple, three of whose Corinthian columns still support the north-west corner of the entablature of the portico inscribed with the letters, Eshom. This temple which, like all the others in the Forum, stands on an elevated podium faced towards the Forum, and concealed a portion of the loggia of the Tabularium. Before its southern corner on the other side of the road which passes in front of it, is the nearly perfect Ionic hexastyle portico of another temple, having its façade at right angles to that of the temple last mentioned; upon the entablature of the Ionic portico may still be read the complete inscription, Senatus populusque Romanus incendio consumptum restituit. Under the cella of the temple are considerable remains of vaulted chambers; in front is a ruined terrace where the steps of the temple must have been, round which the Clivus Capitolinus was carried at a steep incline, continuing its upward course along the north-western side of the temple. The two last described temples are beyond dispute those of Vespasian and Saturn. Antiquarians have differed very much as to their identity, but modern opinion has generally agreed with Canina in ascribing the Ionic temple to Saturn. For the conclusion there seems to be full and sufficient reason, and assuming it therefore to be correct, it necessarily follows that the other Corinthian Temple, and formerly called the Temple of Jupiter Tonans, was that dedicated to Vespasian; it was probably built in the time of Titus and appears to have been restored by the Emperor Severus; in the hall of the Tabularium behind this temple is a doorway which was built up in ancient times and further concealed by the construction of the temple. It gave access to a staircase which is still preserved, and led to the upper floors of the Tabularium without any communication with the lower story. The age of the Temple of Saturn was a much disputed question with the Roman antiquarians; Macrobius says it was dedicated by King Tullus Hostilius, while Varro asserted it was begun by Tarquinius Superbus and dedicated by Titus Lartius the first Dictator, B.C. 501; Dionysius attributes it to the Consuls of the year B.C. 497; Gellius attributes it to L. Furius, Military Tribune, B.C. 381; but all agree in carrying back its original construction to a remote date. The temple was rebuilt in the time of Augustus by Munatius Plaucus, and though the existing portico is evidently a late and clumsy restoration, it would appear that the character of the building in the time of Trajan was as we see it now. The Temple of Saturn was the Treasury of the Roman government, and the military standards were kept here. It was into this temple that Julius Caesar made a violent entry for the purpose of taking possession of the treasure of the State. Between the Temple of Saturn and the Tabularium is a terrace at a level considerably above the Forum, having at the back a long portico or colonnade built in part against the Tabularium and in part against the retaining wall of the Clivus Capitolinus, which is here above it; behind the colonnade in a series of small cells. The colonnade has been much restored, I believe by Canina, and by the restored inscription on its entablature it appears that this colonnade once contained images of the 12 dio consentes placed here by Vettius a Praetextatus, prefect of the city, A.D. 367; but this in all probability is a restoration of a much earlier shrine, containing, as mentioned by Varro, 12 gilded images, 6 of the gods and 6 of the goddesses. At the level of the road below and approached by a narrow passage on the south-west side of the Temple of Vespasian are a series of cells or chambers; they are supposed to have been waiting rooms or offices for notaries or the clerks or criers of the Ediles—they are called Schola Xantha, a name first found in the apocryphal account of the regions of Rome which passes under the name of Sextus Rufus. The lane running between the Temple of Saturn and the Basilica Julia was the Vicus Jugurarius running from the base of the Tarpeian Rock to the Forum.

(To be continued.)

The Ashbourne Local Board have raised the salary of Mr. Burton, surveyor, from £80 to £75 per year.

* A paper by EDWARD T. ANSON, F.G.S., F.R.I.B.A., read before the Royal Institute of British Architects, June 9, 1879.

OLD CARPENTERS' HALL.

THOSE interested in the few remaining relics of Old London will be concerned to hear that the Old Carpenters' Hall in London Wall is in progress of demolition, and that the remnant of the old frescoes which adorned the walls, besides a beautifully enriched plaster ceiling, are now in the hands of the workmen. The Carpenters' Company is one of the most ancient of the City trade guilds, having been founded in 1428 by Roger Jordan. The Hall was originally built in that year, but we find that the present apartment known as the old hall is certainly of later date in its decorations. Upon one of the shields in the panels of the ceiling the date 1671 occurs, and, from what we can gather, the hall underwent considerable repairs and decorations in 1561, and also in 1664 and '65. It appears to have escaped the great fire of London, which swept away the Drapers' Hall adjoining, and for three years its hospitable company sheltered other guilds within its walls, and it became the Mansion House for the time being. The old hall was oblong in shape, and extended some distance across the new roadway now called Throgmorton-avenue, which has cut off a considerable wing of the original building. The present remains of its splendid plaster ceiling embraces two compartments of panels, one being circular and the other octagonal in shape, divided by richly decorated beams of plaster, with a guilloché on their soffits. Each panel has a deeply moulded and enriched border composed of leaves; the centres are decorated with shields, one bearing the engrailed chevron and three pairs of compasses, the arms of the company; and the other has the name of a master, with the date 1671 upon it. These shields are each surrounded with a triangular scroll work of foliage, with figures of angels at sides modelled in high relief. Boldness and vigour characterise the work. On the sides are margin panels of plainer design, and the compartments are marked by cross beams with circular springings resting upon panelled pilasters in the walls. We observe that the latter are of plaster and encase timber posts, and only the upper portions now remain. Though these plaster decorations are begrimed with dust and dirt, they are yet wonderfully perfect in the upper portions: the mouldings to the pilasters are sharp, and it will be unfortunate if no effort is made to save them from their inevitable doom. The frescoes we have referred to form a long panel, about 1 ft. high, along one side of the hall, and are in three divisions. One represents, apparently, the building of the ark, a carpenter sawing timber, and another King Josiah and workmen repairing the temple. The drawing and colours are discernible, and red and yellow in the draperies and timber are still bright. These wall paintings were first discovered in the year 1845 by some workmen engaged in the hall, and, according to Jupp's "Historical Account," were painted as early as 1570. In that work engravings are given of them. We have no doubt a series at one time surrounded the hall, as the remaining frescoes are just head high, and it is likely that the rough wooden gallery erected round the apartment was the cause of their destruction. As an early example of wall painting in a tolerable state of preservation, we hope every effort will be made to save the frescoes. We understand upon inquiry that the company have been endeavouring to get some antiquarian society to take them at the cost of their removal. The funds of the company are said to be insufficient to be devoted to the preservation of these relics, although we heard it was the intention of the company's architect, Mr. Pocock, to reproduce the ceiling of the old hall in the new building now nearly completed. Ascending the staircase into the wing at the rear, we enter the court-room, which dates about 1664, a long apartment with a richly panelled ceiling, though of less interest than the one below. There is, however, a grand old chimney-piece of oak, with overmantel, composed of side pilasters and ramps. The jamb pilasters are enriched with carved foliage in the panels, and the frieze or mantel is adorned with well carved festoons. The old doorways have pediments, and some capital portraits of masters and wardens are on the walls—one a portrait of W. Partington, Esq., one of the earliest masters of the company. But the vestibule is unique in its way. It was erected in 1780, by W. Jupp, the company's surveyor, the wall decorations being in the style of the Brothers Adam. It is square in plan, with a

domical ceiling. The walls are panelled, and each side is adorned with an emblematic figure in plaster relief in an oval medallion, surrounded by the elegant festoons and enrichments of the period. Over these, in the frieze panels, occur relieve heads of Vitruvius, Palladio, Inigo Jones, Sir C. Wren, with side panels decorated with bas-reliefs of carpenter's tools in groups, all very tastefully executed. The walls are painted of two shades of light-bluish green, relieved by gold. Externally, the building which remains is chiefly of wood, and an interesting example of 16th century architecture, reminding us of Inigo Jones' work. The entrance front facing London Wall is evidently only half the extent of the original facade, as the pedimented centre is now on the avenue side. It is of two orders, rusticated and relieved with pilasters and some good detail. The court-room front is low, and has also a pediment with pilasters upon a basement, and no doubt was originally a conspicuous facade crowned by a handsome cornice. The books of the company show an entry that Sir C. Wren received an invitation to dinner, together with his wife. Besides the architectural remains we have pointed out are some fine panels of oak carving, charged with armorial devices; a massive state chair, richly carved; and an octagonal table of oak, having the date 1606 upon it.

WOOD-WORKING MACHINERY.

WE have recently had brought under our notice a new mortising machine, invented by a Mr. Phillips, brought out under the auspices of Messrs. F. W. Reynolds and Co., the wood-working machinists, of 73, Southwark-street, London, and patented both at home and abroad. Two patents cover the machine: the one affecting the oscillating lever-fulcrum, which brings the first condensation of power on to the extremity of the tools used in mortising, boring, core-driving, and tenoning; but the more important patent is the tool-holder, of which the following description will give a very practical idea of its utility as a *time-saver*, as it will be apparent that no resetting of the wood for core-driving, and no repeated change of tools in the spindle are required, the multiple-action tool-holder itself being always ready for instantaneous adjustment.

Fig. 1 is a perspective view of the tool-holder. Figs. 2 and 3 are mechanical drawings of the same, and refer to the following description—Fig. 2 being a side view, and Fig. 3 a front view:—Imagine the tool-box A (Fig. 3) is the nave of a wheel with four arms, B, C, D, and E, all capable of being turned round on the axle F (Fig. 3), and held in desired position by spring bolt G (Fig. 3). The auger is worked by means of a handle H, which handle is also used for reversing the chisel when mortising, and is held in position by the spring bolt J (Figs. 1 and 2). To cut a mortise, the wood being fixed in the ordinary manner, B is ready for boring if required, when finished take spring bolt G in right hand and turn round D, the chisel, into position, after the mortise is cut, the core-driver E is brought into position in the same manner, and the mortise is thus finished. The several tools are brought into operation with as little trouble as a joiner experiences in shifting his mallet from his right hand to his left.

THE COACHMAKERS' EXHIBITION.

ON Friday last, the Lord Mayor distributed the prizes awarded in connection with the exhibition recently held in the Mansion House under the auspices of the Coachmakers' and Coach-harnessmakers' Company. The Committee of Judges reported that there were 30 competitors in all, with 68 drawings, of which 46 were freehand or mechanical drawings and 22

carriage drawings. The former were much more numerous than on any previous occasion, and they attained a higher average standard of excellence. The special prizes offered for competition among apprentices and young men under 22 years of age were now attracting more notice than formerly, and the work sent in was in several cases very satisfactory. The new art and technical school held in St. Mark's School was doing good work, and, being brought into competition with art classes in the provincial cities and towns, was causing a little wholesome rivalry. The competition in the division of carriage drawings was not so satisfactory. Mr. J. P. Lake, of Howick-place, won the highest prize with two sets of working drawings, showing the construction of every part of a four-horse drag and a dress chariot. The majority of the carriage drawings were by no means satisfactory, and the committee in consequence had withheld the second prize. The principal winners were Mr. William Farr, coach-trimmer, of Salisbury; Mr. George Mundy, of Grantham, coach-body-maker; William Thomas Easton, of Portsmouth; apprentice; Herbert Mulliner, of Leamington, clerk; and Walter Coward, a lad of 15 or 16, who took four or five prizes. Mr. Frederick Chancellor, the Master of the Company, took occasion to tender the thanks of the guild to the Lord Mayor for allowing the exhibition to be held in the Mansion-house, and spoke of the interesting nature of the exhibits. The Lord Mayor said the Coachmakers' Company were showing a good example to the other guilds of the City in thus practically promoting technical education in the particular trade with which they were connected. For himself, he differed from those who thought that such education was best promoted by the rich Companies clubbing together and starting a college. On the contrary, he advised each Company to devote itself to the furthering, according to its means, of the special trade with which it was associated, and he believed that if the guilds did so there would be a great stimulus given to trade in all directions.

NATIONAL WATER SUPPLY.*

By J. BAILEY DENTON.

I VENTURE to express the opinion that, at the present juncture, the only way of bringing to a practical bearing the knowledge in possession of the country, and the evidence given before the several Royal Commissions and Parliamentary Committees on the subject of our water economy in its various phases, is to impress upon the Government and the Legislature that the obligation to provide potable water of unexceptional purity for towns and villages situate within river basins, ought to precede all other considerations in relation to the improvement of rivers and watercourses, and that any action taken for their conservancy must fail in this one all-important point if it does not proceed upon such recognition. It will be observed that in the Bill now before the House of Lords no direct reference is made to water supply, although such is the reciprocal bearing of that object upon river conservancy, that it is hardly possible to deal with one in a comprehensive way, independently of the other, without some prejudicial effect.

The timely proposition of the Prince of Wales that there should be a central permanent commission, whose duty it would be to investigate and collect facts connected with water supply in the various districts into which the United Kingdom may be divided, "in order to facilitate the utilisation of the natural sources for the benefit of the country as a whole," must, I submit, commend itself to every one as supplying, in the most tangible form, the omission of the Rivers Conservancy Bill, to which I have just referred. The suggestion is the more apposite, as it comes at a time when the larger centres of population are not only providing themselves with water to the disadvantage of small towns and villages, but are rendering unfit for domestic use—by pollution—the waters they do not appropriate.

It is an incontrovertible fact that, inasmuch as all rivers are maintained by the outflow of springs, issuing from the water-bearing strata, and by the natural conservation of the rainfall upon high uncultivated surfaces, it is not possible to raise water from subterranean sources,

* Contributed to the recent National Water Supply and Sewage Conference of the Society of Arts.

or to intercept water from high grounds for the supply of populations, without affecting the flow of rivers and watercourses, while it is equally certain that any acts of conservancy which may lead to the more rapid discharge of watercourses descending from the hills to the valleys, will prejudicially affect the local water supply of the districts through which these watercourses pass. At the same time, it is known to those who have carefully studied the earth's stratification, that such is the alternation of pervious and impervious strata throughout this country, that there hardly exists a river basin wherein, by special works of combination or otherwise, towns and villages may not be economically served with water without any appreciable effect upon our river systems.

What is now wanted is the record, in an intelligible form, of such hydrogeological information as is already in the hands of the Geological Survey Department, to be supplemented from time to time with additional details. This would furnish the most useful data in the hands of any Commission which may, on the suggestion of H.R.H. the Prince of Wales, be formed, and would make every one familiar with the underground sources of supply.

A GRAMMAR OF JAPANESE ORNAMENT.*

WE have lately noticed several works of a decorative character, and not a few upon Japanese ornaments, and we have now another upon our table bearing the above title. By a grammar we naturally understand a work treating of fundamental principles, or, at least, a collection of examples that shall indicate the formation of a style of ornament. Mr. Thomas W. Cutler's work, the first part of which is before us, is a collection of examples of a somewhat mixed and disursive character, and in the absence of the barest descriptive letter-press, we can hardly understand the claim it has to be called a grammar. But we take it as the first instalment. The plates are not numbered in consecutive order, but contain a selection from a comparatively large number, and, from what we can see of the first part of the work, it promises to be one of real artistic merit. The first plate represents some picturesque groupings of the crane, a bird held in veneration by the Japanese, and accepted as the emblem of longevity. We find the group No. 2 is a reproduction from an old Japanese work in our possession; it has been very faithfully copied by the artist, even to the shading of the birds, though the darkly-shaded parts in the original are not so black, and there is a half-tint that lessens the sharpness of the shadows against the lighted plumage. The black shadows are a little too harsh. It is well known that the Japanese artist is particularly skilful in the representation of birds, either by themselves, or combined with vegetable forms; they are grouped in every conceivable manner, and every posture and action is watched with a keen artistic appreciation. Besides the crane, the wild duck, the peacock, pheasant, and the common fowl, and smaller birds supply an exhaustless variety to the artist. Messrs. Audsley, in their magnificent work "Keramic Art of Japan," allude at length to the treatment of birds, and one of the most favourite modes of representing them is that in a group or resting, as in the examples given by Mr. Cutler. Plate 2 shows another example of a bird upon a branch, well adapted for screens, wall decorations, &c. Plates 3 and 4 illustrate other varieties of the feathered tribe, either at rest or on the wing, and a conventionalised study of them. Mr. Cutler has carefully assorted the elements in each kind of representation; he has shown the idea of height and cloud by the introduction of the favourite sprigs of fir, bamboo or "mume," and the conventional cloud in some cases. In foliage and flowers we find a few choice and suggestive examples, several plates being devoted to vegetable forms. The *kiku*, or chrysanthemum, the wisteria, the *butan* or peony, the iris, the *kiri*, the *mume*, the fir and other forms are found. The fir is of as frequent occurrence in lacquer and bronzes as the chrysanthemum. Plate 50 shows a striking treatment printed upon a brown ground, suitable for wall papers and textile fabrics, and the sprays of foliage on plate

38 are thoroughly characteristic of the Japanese spirit and scheme of decoration. We note a variety in the printing of the illustrations, and for artistic reasons we prefer those printed in a light shade of brown or grey, to those in black. The birds on Plate 3 would have been infinitely more pleasing in the light tone adopted in Plate 4; the harsh black shaded portions in figures 5 and 6 are destructive to the feeling of the Japanese work as displayed in native illustrated books. Plate 14 is the least pleasing in the number before us, and 49 has little Japanese *motif* about it. Remarkably quaint is the conceit shown depicted on Plate 13; it is thoroughly Japanese in idea at least, and we hardly know which to admire the most, the grotesque combination of the fish and the stream, or the humorous mode of conventional delineation. Mr. Cutler's work is bound in a wrapper, thoroughly expressive of the style, if we cannot say the design is imbued also with its sentiment. For the first part of a grammar of ornament, a little more of the intention of the author and the scope of the work might be expected; as the work proceeds there will be an opportunity for development, and we may fairly expect even better and more suggestive examples to follow. It is because of its purely suggestive character that the style of Japan is useful to the decorative artist; to copy it unmeaningly in our papers, china, and textiles would be to bring it into deserved ridicule, and to hasten its rejection by all artists worthy of the name. It is admirably suited for decorative work or simple flat surface ornamentation; and a grammar that will afford insight into the mode of designing of the Japanese artist, and give illustrations of conventional forms rather than studied grotesques, will be of considerable value.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

BIRMINGHAM ARCHITECTURAL ASSOCIATION.—The closing meeting of session 1878-9 was held on Monday evening. Votes of thanks were passed to the retiring officers for their past services. The following were elected as officers for the ensuing session:—President: Mr. William Hale. Committee: Messrs. R. B. Morgan (chairman), A. Freeman Smith (treasurer), Fred. G. Hughes (hon. secretary and librarian), F. W. Cross, O. Essex, W. H. Kendrick, H. H. McConnal, J. P. Osborne, A. Reading, and E. Wood. Messrs. W. G. Mantle and T. Jones were appointed auditors.

BRITISH ARCHÆOLOGICAL ASSOCIATION.—The twelfth meeting of the Session was held last Wednesday, Mr. Syer Cuning, F.S.A. Scot., in the chair. It was announced that Lord Waverley had been elected President for the year, and that the Congress had been fixed to commence on the 11th of August, at Great Yarmouth, ending at Norwich on the 20th. A large number of antiquities were exhibited, including some interesting Roman remains from Southwark by Mr. Way, a gilt crucifix discovered in the City by the Rev. S. M. Mayhew, and a perfect Norman jug from Cheapside by Mr. Loftus Brock, F.S.A. It was ornamented by bold diagonal lines and flowers laid on in slip. The first paper was by the chairman, who described one of the figures on a richly-embroidered chasuble of the close of the fifteenth century, found in 1825 in a walled-up crypt beneath Warrington Church. The figure represented St. Thomas, Earl of Lancaster, beheaded at Pontefract, 1322, after being taken prisoner by the Royalists. He is represented in armour of the period, and with a battle-axe. In the northern counties he was considered to be a martyr to the public cause, and was called a saint. Pilgrimages were made to the hill on which he suffered, and a particular office of Mass was drawn up for the celebration of his festival. The second paper was by Mr. C. H. Compton, and descriptive of the Company of Horners of the City of London, a company which, instead of being extinct as has been said on high authority, is still extant. The antiquity of the craft was referred to, and it was shown that Horners were classed among the eight mysteries of the City, temp. Edward III., but the company was not incorporated until 1641. It ceased to be a trading company between the years 1745 and 1796. It never possessed a hall, although it is authorised to build one. The livery is limited to 60, but between 1808 and 1833 only 14 members had been admitted. Some

deeds of the time of Elizabeth and articles of horn were exhibited. The concluding paper was by Mr. J. T. Irvine, who described the results of a journey made along the course of the Wansdyke from Bishops Canning in the direction of Bath. The earthworks are in places remarkably perfect, showing a high bank with a deep narrow ditch, so narrow in fact as to disprove the theory that it could ever have been used in part of its course for the main Roman road to Bath.

LEEDS ARCHITECTURAL ASSOCIATION.—At a meeting of this association on Thursday week a paper, entitled "The Renaissance in England," by Mr. John J. Stevenson, F.S.A., London, was read, in the absence of the lecturer, by Mr. William H. Thorp, hon. secretary. The paper treating upon the Renaissance of Classical architecture in England is one of the chapters of a book on Domestic Architecture, of which Mr. Stevenson is the author. In the commencement of the paper the lecturer stated that "the new architecture, in anything approaching the purity of the Italian style, took root in England, as the accepted style for ordinary buildings, later than in any of the countries that had already been spoken of, namely, Italy, France, Holland, and Belgium." The English are a conservative people. The native style was strong and vigorous, sensible, suited to domestic wants.

COMPETITIONS.

GLOUCESTER.—The designs for the new Gloucestershire pauper lunatic asylum, proposed to be erected on the Barnwood Mill Estate, have been sent in to the office of the Clerk of the Peace for the County at Gloucester. About thirty architects have taken part in the competition, and the drawings are at present arranged in the Shire-hall for inspection by the Visiting Justices of the asylum, with whom rests the selection. The premiums offered are, first £150 and second £70. It is intended only to erect at first the administrative block and such portions of the buildings as may be immediately needed for patients, but the designs are to show for the completed scheme.

IPSWICH POST-OFFICE.—We understand that the report of the referee (Mr. C. Barry), to whom the designs for the Ipswich Post-office have been referred, will shortly be made public. The design of "Well Considered," which from the first was a favourite with the Committee, is we believe the one recommended in Mr. Barry's report. Our review of the competition designs spoke of this one as the most expensively treated externally, and now we hear the element of cost has been sunk altogether, as Mr. Barry finds what we before said, that the sum of £6,000 is insufficient for the purpose. We presume, therefore, the merits of the designs alone have been taken into consideration in making the award; but this opens a new question, in which all the competitors may have a word to say. One of the strongest points which has gone in favour of "Well Considered" is, we understand, the manner in which the drop in the level of the public office portion has been managed. The author has wisely pronounced this part of his elevation by a pediment. In the new Library and Museum Competition, noticed elsewhere this week, we recognise the same hand in the design marked "Simplicity."

KINGSTON-UPON-HULL.—BOROUGH LUNATIC ASYLUM.—The Committee inform us that the time for sending in plans for the above asylum has been extended to the 21st of July.

At the suggestion of Mr. Ewan Christian, under whose supervision the collegiate church of St. Peter, at Coggeshall, North Essex, was restored, the memorial to the late Vicar of Coggeshall will take the form of a carved oak chancel screen, with light mullions, open arches, a rich cresting above, and panelling below.

Christ Church, Preston, is about to be restored from the plans of Mr. Joseph Harding, of that town. It is proposed to re-shape and lower the pews, to build an organ chamber on one side the chancel and a choir and minister's vestry on the other, and to remove part of the side galleries.

The Wimborne highway board have elected Mr. Robert Seymour, of Little Canford, as surveyor at a salary of £180 a year. There were over 70 candidates for the appointment.

* A Grammar of Japanese Ornament and Design. By THOMAS W. CUTLER. London: B. T. Batsford.

Building Intelligence.

BAXENDEN, NEAR ACCRINGTON.—The corner-stone of St. John's Schools was laid on Saturday last by Mrs. H. W. Worsley, of Chislehurst. The building will be built of stone, and comprises a large room for boys and girls, two classrooms, and book closets; adjoining the west side of school is a master's house, containing sitting-room, kitchen, scullery, and bed-rooms over the same. The schools will have accommodation for 400 scholars, and will cost about £3,500. The style of architecture is Gothic of a simple character. The works are being carried out by local tradesmen from designs prepared by Mr. William S. Varley, architect, Blackburn.

BRISTOL.—The old church of St. Thomas, Bristol, has undergone an extensive restoration. The new works include the substitution of new open benches of oak for the old high pews, and the heating of the building by hot water. One bay of the old nave has been arranged as a chancel, enclosed by carved open screens of oak, walnut, and sycamore. The chancel has been fitted up with carved choir seats and a new altar. A new font of stone and marble has been provided. The whole of the floor not occupied by seats is laid with Maw's tiles. The altar piece, erected in 1716, and the choir gallery, in 1728, have been cleaned from various coats of black varnish. The walls and ceilings of the entire church have been effectively decorated in oil colours; on the walls of the chancel are painted the figures of St. Augustine of Canterbury, Thomas à Becket, John Wicliffe, and Bishop Butler, being all of them connected with the history either of the church or neighbourhood. The architect under whose superintendence the works have been carried out is Mr. W. V. Gough, of Nicholas-street, Bristol. The total cost of the entire work is £3,500.

CHESTER.—On Tuesday week the memorial stones of a new Baptist chapel at Chester were laid. The building will consist of a chapel 43ft. wide by 56ft. long inside, with porches at each side to the front and vestries at the back. There will be a schoolroom underneath, the same size as the chapel above. The materials used for the outside are red Ruabon bricks for the walling; the dressings for doors, windows, strings, &c., of stone from the Cefn quarries, and the roofs are to be covered with brown tiles. The interior of the chapel is intended to be finished with buff brick. The contract has been let to Mr. D. Sheen, and the building has been designed and will be carried out under the superintendence of Mr. John Douglas, of Chester.

EDINBURGH.—The erection of the spire of St. Mary's Cathedral, Edinburgh, was formally completed on Friday afternoon by the adjustment of the cope-stone. Springing from the tower of the cathedral, which itself is 112ft. high, the spire, a stone structure of octagonal form, is carried up till the height of 275ft. is attained, and above the cope-stone there is to be placed an iron cross 15ft. high. In the junction of tower and spire a somewhat unusual arrangement has been followed, the tower being changed from the square to the octagonal form at the bottom of the belfry, a stage lower than that at which the spire proper commences. At the point where the change of form is effected, stone pinnacles each 50ft. in height and about 9ft. 6in. in diameter, are reared over the four corners of the tower. At the base of the spire richness is given to the design by the introduction of four niches, each containing a sculptured archangel, 9ft. 6in. in height, and, alternating with these, as many Gothic windows, artistically treated with gables surmounted by crosses. Over these the stonework is carried up in the ordinary way, till it terminates in a large carved finial supporting the crowning iron cross. The work in this part of the cathedral has occupied eight months, but, of course, had the winter been less severe, it would have been completed some time ago. The scaffolding is itself a work of some interest. It is constructed of Norway fir specially imported for the purpose, and, while remarkably light, in comparison with the cumbersome erections often seen round similar buildings, is at the same time perfectly secure.

FALKIRK.—Last week the memorial stones of a new Masonic-hall and new Town-hall were laid at Falkirk. The Masonic-hall joins the east wing of the Town-hall, and the front elevation is in

harmony with its style of architecture. The Town-hall is in the Italian style, and measures in the interior 87ft. by 44ft. The upper part of the hall measures 94ft. by 65ft. The ceiling is divided in panels, with ornamental centre flower, and the roof supported on cast-iron columns. The hall is seated for upwards of 1,600. The cost is over £4,000. Messrs. A. and W. Black, Falkirk, are the architects.

GATESHEAD.—The foundation-stone of new day industrial schools was laid on the 5th inst. The new buildings are designed to accommodate 100 boys and 100 girls, and are two stories high. Red bricks is the material employed, with stone dressing, and slated roof. The entrances, staircases, and corridors will be fireproof, and various portions used by the children will be heated by hot water. The general contract for both schools has been let to Mr. Alexander Thompson, of Gateshead. The buildings have been designed by Messrs. Oliver and Leeson, architects of Newcastle-on-Tyne.

GREAT HARWOOD.—New Congregational Sunday and day-schools were opened in this place on Saturday. The schools have been erected from the designs of Mr. W. S. Varley, of Blackburn, and seat 700 children, under the Government regulations, although at public meetings nearly 1,000 persons can be accommodated. They consist of a schoolroom 73ft. by 35ft.; infants' room, 52ft. 6in. by 35ft.; and babies' room, 30ft. by 15ft.; five class-rooms, each 15ft. by 14ft. The rooms are each 13ft. high in the square, and 22ft. 6in. to ceiling. Porches fitted as hat and cloak-rooms are provided in each school, and beneath the infants' room are heating vault and coal-store. The walls are of pointed rubble, and the dressings are of ashlar from local quarries. A dado of polished pitch pine is carried round each room to height of window sills. The roofs are of varnished pitch pine, ceiled at the collar beam, and covered with blue Velineli slates. The windows are glazed with fluted-rolled plate-glass, having iron ventilators sashed in same. The warming is by hot water on the low-pressure system. The chief contractors are—masons, Messrs. Maden and Butterfield, Accrington; joiner, Mr. Daniel Birtwistle, Great Harwood; slater, Mr. Thornley, Church; plumbers, glaziers, painters, gasfitters, and hot-water engineers, Messrs. Harley and Hartley, of Great Harwood. The total cost, inclusive of boundary walls, formation of play-yards, galleries, &c., has been about £2,000.

LYNN.—The Corn Exchange at Lynn has been considerably improved so far as the roof is concerned, which has been constructed and glazed on Rendle's new principle, entirely dispensing with the use of putty or any other cement. The length of the roof (which is constructed of iron) is 170ft., by about 28ft. wide on either side, and contains an area of nearly 9,000ft. superficial of the patent glazing. The increase of light is nearly 50 per cent. over the old method, and the appearance is vastly improved by the removal of the heavy sash bars for the small vertical tubes which are used in this system. There is a lantern on the summit of the roof, which affords ventilation to the building by means of "louvre" boards. The whole work has been carried out by Mr. W. E. Rendle, of 3, Westminster Chambers, London, who is the patentee of the system. His patent is now used by most of the railway companies, Her Majesty's Government and the leading architects and engineers. He has already supplied two million square feet of his patent glazing; and one station (the Carlisle citadel) which will shortly be commenced, will cover seven acres, and contain an area of 350,000ft. super.

NEW ROMNEY.—A public meeting was held at New Romney, Kent, on Wednesday week, for the purpose of considering the question of restoring the parish church. Mr. G. Gilbert Scott, F.S.A., read a report prepared by his late father, setting forth the architectural history of the building, and the reparation he deemed necessary. The amount required for the entire restoration of the fabric, exclusive of fittings, was estimated at from £3,500 to £1,000, but the work, it was suggested, might be divided into sections. A resolution appointing Mr. G. G. Scott architect for carrying out the plans of the late Sir Gilbert Scott was carried unanimously, as was another appointing a local committee.

TORQUAY.—A new Wesleyan chapel at Torquay was opened on Thursday week. The style adopted

is Classic, freely treated. The chapel on the ground-floor is 79ft. by 50ft. Accommodation is provided for about 1,000 persons. A school-building is erected on the higher side of the chapel. The buildings have been very creditably carried out by the contractor, Mr. E. P. Bovey, of Torquay, the carving being executed by Mr. H. Heus, of Exeter. The architects were Messrs. J. Rowell and Son, of Newton and Torquay, Mr. E. Richards, their assistant, having attended to the carrying out of the details generally. The cost of the building has been about £6,000.

WIGAN.—The foundation-stone of the new church of St. Andrew, Wigan, was laid last week. The new edifice, the general character of the architecture of which will be Early English, is designed to accommodate 580 persons. The church will comprise a nave 26ft. 6in. wide, and 70ft. long, with aisles on each side 10ft. wide; a chancel 27ft. 6in. wide, and 34ft. long. The chancel will be the same height as the nave, and separated from it by a screen, and a double principal in the roof. On the north side of the chancel there will be a large aisle, and on the south side the organ chamber and vestries for the choir and clergy. The interior of the church will be upwards of 55ft. in height to the apex of the roof. The general entrances will be to the west of each of the aisles, while a separate entrance will be provided for the vestries. At the north-west angle of the nave the bell-tower will be situated. The church is to be built entirely of brick with the exception of some small portion of the windows and the pillars for the arches. The interior will be finished with red pressed bricks relieved by moulded bricks and dark brick bands. Mr. F. W. Hunt, of London, is the architect. Mr. W. Winnard, of Wigan, has been entrusted with the contract. Mr. Varty is clerk of the works.

YORK.—The foundation-stone of a new Primitive Methodist Chapel was laid on Whit-Monday at York. Mr. Wm. Peachey, of Concy-street, York, is the architect of the new edifice, which will seat 900 persons. The style is Renaissance, carried out entirely with red and white pressed bricks, with a little terra-cotta. The ground-floor is seated in amphitheatre form, all the seats curving from the point at which the minister stands upon the rostrum. There will be a gallery upon the four sides, that behind the rostrum being appropriated for the organ and choir. The interior height is 38ft. to the centre of the ceiling, which consists of three curves relieved by moulded and enriched plaster beams springing from a moulded cornice. Four vestries, with the usual conveniences, are provided below the organ gallery, &c. The total cost will be about £3,000.

CHIPS.

A group of children's houses have just been built for Miss Cotton, in Davis-lane, Leytonstone, from the designs of Mr. Streatfield. They are arranged as a quadrangle, built in on all four sides, and are in three floors. Mr. Parminster, of Braintree, was the builder.

The Royal Hotel, Great Yarmouth, has just been enlarged from the designs of Mr. Pearce, of Norwich. The additions consist of a billiard-room, 36ft. by 28ft., fitted in mahogany, with coved and panelled ceiling, and arranged for two tables; a ladies' drawing-room, and above the latter two floors of seven bedrooms each. Mr. Edmund Howes was the builder, Mr. Harrison the mason, and Mr. Cooper the carpenter.

The formal opening of the restored church of Stratford St. Mary, Suffolk, took place on Thursday week. The east end of chancel has been rebuilt, and the chancel floor raised; a roaredos has been erected, having an arcade of open tabernacle work and a super-altar of polished Devonshire marble; new handsome carved oak screens and sedilia altar-table, pulpit, and lectern have also been placed in the chancel, and the whole church has been paved with Minton's tiles. The south aisle has been rebuilt, the clerestory renewed, and parapets corresponding with that on the north aisle added to the whole church; the roofs repaired and reconstructed, and Porritt's warming apparatus has been introduced. The work has been executed under the direction of Mr. Woodyer, of Guildford.

The church at Kemerton, near Tewkesbury, was rebuilt in 1847, with the exception of the tower, the lower part of which dated from the 11th century. This has just been restored from the designs of Mr. W. White, F.S.A., the work being carried out by Mr. Collins, of Tewkesbury, except the re-hanging of the bells, undertaken by Messrs. Mears. The reopening services took place last week.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Two pence, of all bookellers and news-vendors. Post free 2½d. Office: 31, Tavistock street, Covent-garden W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33f. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

"BUILDING NEWS" DESIGNING CLUB.

Press of matter obliges us to postpone our review till next week.

DRAWINGS RECEIVED.—Several other drawings have come to hand since the publication of our list last week.

AN INTENDING COMPETITOR. (The wash and bakehouse may either form a distinct building for the row or be attached to each cottage. The former was intended.)—MAURICE DEACON. (Get Mr. Baldwin Latham's "Sanitary Engineering," published by E. and F. N. Spon, 48, Charing-cross.)

Correspondence.

A SINGULAR STOUP.

To the Editor of the BUILDING NEWS.

SIR—The out-of-the-way parish church of Lewanick stands upon a hill in a remote part of Cornwall, full six miles from the nearest railway station. It is situated in the immediate neighbourhood of the Polliprant Quarries, and of that stone the church, in the main, is built. Mostly of a Perpendicular type—how few Cornish churches there are that belong to any other style!—its pinnacled tower is of noble proportions, and, although essentially a West-Country building, there is much that is otherwise of decided interest pertaining to the edifice. Upon the splay of the stone seat in one of porches a hare hunted by hounds is vigorously carved, and a large Norman font, octagonal, and just 3ft. over, stands, in a capital state of preservation, at the west end. The bench ends are all old and boldly carved on face and on mould, those at the angles of the aisles and central avenue, east and west, having further carved terminations, each consisting of winged angels kneeling in attitudes of adoration. This treatment is rare, by the bye, for the West-Country bench-ends are almost invariably found to be square-headed and without standards. Indeed, poppy-heads are so seldom met with, that in the whole of Devon I only remember, for the moment, St. Mary's, Atherington, and St. Michael's, Ilminster, as affording samples of foliated terminations. Fur-

ther, the local ends are always found to be in the solid, 3in., 3½in., 4in., and even of greater thicknesses. Framed ends, such as one meets with sometimes in the Midlands, and elsewhere, have no counterparts in the extreme West. But, to my text. Near to the north-west porch at Lewanick Church, within the building, and close to the book-board end of the old seating, is a very curious stoup. Here it is:—It is of polished

granite, but of a much finer and a better sort than is that the immediate neighbourhood provides. The seven holes in the top, shown upon the plan, are each 2½in. wide and 3½in. deep. Are they symbolical of the seven churches, and do similar stoups still exist elsewhere? To me this one is unique.—I am, &c.,

HENRY HEMS.

GLOUCESTER ASYLUM COMPETITION.

SIR—I am informed that the firm of which the County Surveyor for Gloucestershire is the senior partner are competing for this work, and also that before the competition they prepared a design for the proposed asylum by the instructions of the magistrates. Now, I venture to think, that this is doubly unfair. In the first place, I do not think it is right that the salaried officer of any public body should be allowed to compete in a matter where such public body are the judges; and secondly, I think it is unjust that professional men who have been consulted prior to a competition should afterwards be allowed to compete.

On both grounds there will be an uncomfortable suspicion that if even these gentlemen should succeed in keeping their motto secret, they will, from their official position, and from their previous engagement on the undertaking, have unfair advantages over other competitors, and I therefore hope that the magistrates will at once remunerate them for their services, previous to the competition, and eliminate their design from those now sent in.—I am, &c.,

A COMPETITOR WHO ONLY WANTS FAIR PLAY.

A GOOD EXAMPLE.

SIR,—I had much pleasure in reading the remarks you published in last week's issue. I with a number of working men passed some hours in Messrs. Wright and Mansfield's spacious show rooms examining their splendid work.

Will you please give me a space to make known the generous act of a firm of employers of labour to open their show rooms two evenings until ten o'clock for their own and other workmen to inspect their furniture and decoration? This unselfish act gave great satisfaction, and many hundreds of workmen availed themselves of the opportunity, and no doubt profited by the exhibition. I assure you, Sir, if employers could have seen the interest taken, and heard the remarks made they

would be convinced of the pleasure it would give us if such a useful example were followed by other firms.—I am, &c.,

F. FOWLER.

8, Windmill-street, Tottenham Court-road.

Intercommunication.

QUESTIONS.

[5794.]—**Timber.**—Can any of your readers inform me of the name and publisher of any book which gives the most thorough description and use of all English and foreign timber?—READER.

[5795.]—**Portland Stone in Temple Buildings.**—In looking at those buildings a few days since I was much struck by the smudgy appearance of the joints, which I can only compare to the sloping in of brickwork when prepared to stain for bastard tuck pointing. Upon inquiry two reasons have been assigned, neither satisfactory. 1st. It is said it is the work of the foreign masons during the late strike, and 2nd, that the work was fixed over hundred—i.e., no outside scaffold. Neither of these seem to me satisfactory, and I should be glad of an explanation; for the difference between this building and the neighbouring library is so marked that one would like to know why.—NOVICE.

[5796.]—**Tenants.**—Will some reader kindly explain the meaning of "tenant by elegit," "statute merchant staple," "in fee simple," and "in-tail" also? What is the meaning of a "continuing" Covenant?—L. T. W.

[5797.]—**Baths.**—Can any reader inform me what is the best construction for sides and bottom of a public swimming-bath (say, 100ft. by 40ft. inside) so as to make it thoroughly water-tight? Some I have seen fall as much as 2in. in the twenty-four hours.—C. W. B.

[5798.]—**Cement and Mortar Stains.**—Will any reader kindly inform me of the best method to remove cement and mortar stains off common Staffordshire tiles?—A. B. C.

[5799.]—**Architectural Examination.**—Will some reader inform me where I can obtain a copy of the questions asked in the preliminary section of the architectural examination?—S. D.

[5800.]—**Sgraffito Work.**—Could anyone give me such information as will enable me to execute a piece of sgraffito work? I wish particularly to know what kind of cement is used, what kind of colours are necessary (I should like to produce some very light tints), in what particulars the method of working differs from ordinary plastering (either for internal or external work), and if it is possible to guarantee that the colours will stand the washing of the rain, and the cement the frost.—A PLASTERER.

[5801.]—**Cellar.**—What would be the best means of proceeding to construct the lower part of a cellar, the floor of which is required to be 2ft. below the sewer in the road? Of course, I don't mean to drain it, but to prevent moisture, &c., penetrating the walls.—RIGRU.

[5802.]—**Lunatic Asylum.**—The name and situation of the most recently built lunatic asylum on the "block system" will oblige.—H.

[5803.]—**Proportion in Church Architecture.**—Will any reader name a good work on the above or give the following:—Proportion of nave as regards length to width, height to wall-plate and to ridge, also of chancel to nave, &c., and of towers and spires generally? Any definitions would greatly help.—PERPLEXED STUDENT.

[5804.]—**Circus.**—Can any reader kindly inform me what materials are used for building the arena of a circus ring, also the depth required, and if there is any fixed diameter?—ISQUAER.

REPLIES.

[5728.]—**Coloured Stones.**—I am scarcely satisfied with the replies on this question. There has been a little too much of "red" imported, and yet an indeliteness even as to reds. I have since noted the large columns at the foot of the steps in Queen Victoria-street, at the Church of St. Andrew's by the Wardrobe, which are showing marked decay, and have been there only a few years. Is this Corshill? But as to coloured stones, the old offices of the "Crown Insurance Co.," in New Bridge-street, and the new offices near St. Dunstan's Church are good examples; but what are they? If some correspondent will enlighten us upon this, many of your readers will be glad. Could any information be obtained and samples seen at the Geological Museum?—J. W.

[5775.]—**Heating Kiln.**—Will J. A. Buck kindly furnish the following information as to the heating kiln he recommends:—What would be the cost of apparatus? The cost per diem of fuel consumed. The chamber to be heated would be 14ft. by 14ft. by 12ft. All the heat should proceed from below the level of the floor, the interior containing racks on which are placed frames for drying herbs. The greatest heat required would not exceed 140°. Perhaps "J. A. B." would say if in his opinion the apparatus of which he speaks is fit for the purpose.—H. D. II.

[5786.]—**Edington Church.**—In reply to "W. P.," we beg to say that the church of St. George, which has recently been pulled down and rebuilt, cannot be the very interesting church erected by Bishop Edington. This bishop lived during the middle of the 14th century, whilst the oldest portions of the old church in question were certainly not built before the commencement of the 16th century. It is therefore quite clear that this was not "the valuable stepping-stone in the history of English Architecture" that "W. P." imagines. He has apparently mistaken the Edington in Wiltshire, which has, we believe, a very fine specimen of an old village church, for Edington, near Bridgwater. We cannot find that Bishop Edington had any connection whatever with the last-named village.—EDWIN DOWNS AND SOX.

[557.]—Strains on Collar-Beam Roof.—Let us take a sketch, A, for an example with the collar—say,

6ft. long, and the rafter above it 5ft. long, and the height of ridge above the collar equal to 4ft., and let us consider the same as if the collar rested on the wall, and for the present suppose the walls to be only 6ft. apart. Then for a given length of roof covering to same assume the weight equal to one ton, then half a ton will bear on the walls and half a ton will exist at the ridge, being $\frac{1}{2}$ of a ton on either side, but this half ton will also be eventually carried by the walls, but will first exert its weight as follows:—The tops of the rafters will bear against each other with exactly the same power they exert against each other on the collar. And if the vertical pressure at the ridge is equal to $\frac{1}{2}$ of a ton on one side, then the horizontal strain on the half of the collar will be equal to $\frac{1}{2}$ of the $\frac{1}{2}$ ton = $\frac{1}{4}$ ton = $3\frac{1}{2}$ cwt. being in the ratio of half the length of the collar to the height of ridge above same, or in our case as 3 is to 4. It will be evident that the strain on the collar can only be equal to that we have already obtained, and which is due to the pressure on one side only by considering that the strains would be exactly the same if one side were a lean-to, fixed to an immovable wall, because as one side is as strong as the other neither side can exert a greater strain against the other than that due to its own weight, because otherwise it would overpower the other, which is equally powerful. If our rafters were already left below the collar one half their length above or equal to 7ft. 6in. long, and if we were to take this roof off the wall's 6ft. apart and put it on walls 9ft. apart, then there would result as per sketch, B,--wherein the roof is turned the reverse way up, as I think it may perhaps be thereby more readily realised—say, weight of roof $1\frac{1}{2}$ tons, and the sketches will explain themselves. But I will remark that the half of each rafter will place on each wall another $\frac{3}{4}$ ton, and which will be resisted as much as it resists, and therefore does not appear in the sketch; but the $\frac{3}{4}$ ton on each side which does appear is that which is resisted by the wall, but also resolves itself into horizontal pressure, and is equal to the $\frac{1}{4}$ ton strain at the plate level or to

$\frac{27}{64}$ ton strain at the collar. If the pitch be only half as much the strain on the collar will be double for the same weight—say, 17cwt.—and if to the given weight there be 17 collars, we shall have 17wt. strain on each, which a $\frac{1}{2}$ in. bolt nut and washer would more than equal.—HENRY ANDREWS.

[5790.]—Quantity Surveying.—It would depend much on the nature of the stonework of the building mentioned by "W." as to whether it took a long or short time to take out. But if only restricted to jambs, sills, and strings, I should think it could be easily worked off in 90 hours, that is supposing it to be abstracted and filled as fast as each trade was finished. It is best to commence with the joiner, as it gives more items for the abstractor.—E. C. P.

STATUES, MEMORIALS, &c.

WOLVERHAMPTON.—A statue of the Right Hon. C. P. Villiers has been unveiled at Wolverhampton. It is placed upon a pedestal of gray granite, weighing twelve tons, and is of colossal dimensions, measuring nine feet in height. It is chiselled in Sicilian marble, and is from the studio of Mr. William Theed, R.A. The cost was £1,000.

LEGAL INTELLIGENCE.

WHAT IS A HIGHWAY?—The Board of Works for the Poplar District v. the North Metropolitan Tramways Company.—This was an appeal from an order made by Mr. Lushington, the Thames-street Police-court magistrate, and was heard in Queen's Bench Division on May 14th, before Lord Chief Justice Cockburn and Mr. Justice Mellor. Before the magistrate a complaint had been preferred under the 75th Section of the Metropolitan Management Amendment Act (25 and 26 Vict. cap. 102), by the Clerk to the Poplar District Board of Works against the respondents that they had unlawfully erected stables beyond the general line of building in Blair-street, Bromley St. Leonard's, without the consent of the Metropolitan Board of Works, and the complaint had been dismissed with costs. It was then proved by the appellants that Blair-street is one of numerous roads laid out on a building estate; that it was opened for public traffic in January, 1877, and was lighted by public lamps, and that the sewer had been vested in the appellants, by whom connections with the houses had been sanctioned. It was further proved, that during the progress of the building of the stables in question, and about May, 1878, notice was given pursuant to the 76th section of the Metropolitan Management Act, 1855, by the builder, of the intention to build and drain, and that the appellants approved of the plan for drainage, and informed the said builder thereof, at the same time warning him that the buildings were in advance of the proper line, and that application should be made to the Metropolitan Board of Works, if it was desired to build up to the proposed line of building. This the respondents did not do; but without the sanction of the Metropolitan Board proceeded to build, bringing the walls within 50ft. from the highway. Blair-street is a "street" within the meaning of the Metropolitan Local Management Acts, 1855 and 1862. It is 40ft. wide, including footways, and except one vacant corner plot, has a continuous line of houses and buildings in various occupations on each side thereof, all of which buildings were erected, or in course of erection, in the summer of 1878. It is also a "new street" within section 112 of 25 and 26 Vic. cap. 102, the paving and the construction of the roadway being still incomplete, and the maintenance of the paving and roadway having so far been at the sole expense of the freeholder. The buildings erected by the respondents came up to and abut on the footway, but are about 5ft. in advance towards the centre of the street of the general line of buildings in the same street, as decided by the superintending architect of the Metropolitan Board of Works. The appellants contended that the 75th section of the Metropolitan Management Amendment Act, 1862 (25 and 26 Vic. cap. 102), applied to all "streets" within the Metropolitan, whether highways or not; that the fact of the *locus in quo* being laid out as a street for public traffic, conferred jurisdiction upon the superintending architect of the Metropolitan Board of Works to decide on the general line of buildings therein, irrespective of the question of property in the soil in the street; that the facts as to the lighting and sewerage executed by the appellants in the said street, showed conclusively that the 75th section applied, and that it was immaterial that the street had not become a highway. The respondents, on the other hand, contended that Blair-street being the freehold property of an individual, to which the public was admitted as of favour and not as of right, there being no dedication of the street to the public by user or otherwise, and it being within the freeholder's option to bar the access of the public to the street by the erection of gates or other proper method of obstruction, if it pleased him, it was not a highway at all within the meaning of the sections of the before recited Act. The magistrate was of opinion that the words of the 75th section implied the necessity that the street on which the building was erected should be not only a street, but a highway, to bring it within that section; that the acts of sewerage and lighting by the appellants being done by them under the powers and obligation respectively arising from the 69th and 130th sections of the 18th and 19th Vic., cap. 120, were no evidence that Blair-street had been dedicated to public use as a highway; and, in the absence of any such evidence, that the user shown was not sufficient to found a presumption of dedication, and that the freeholder had still a right, if he chose, to put up a bar across the said still unfinished street, and prevent the use thereof by the public. For these reasons the magistrate held that in deciding the general line of buildings in the street, the superintending architect of the Metropolitan

Board of Works had gone beyond his powers, and the respondents were, therefore, improperly summoned. The question turned on what is and what is not meant by a "highway" in the 75th section of the said act; Mr. Kemp, Q.C., for the respondents, contending that the word in the section referred to turnpike roads, and to such roads over which all the king's subjects have a right of passage. Thus Blair-street might be a street, but was not necessarily a highway. For the appellants Mr. Philbrick, Q.C., had urged that this section has reference to the ventilation of the streets and possibly to their architectural uniformity, and not at all to their use as a highway. The Lord Chief Justice considered that the word "highway" was used in the Act in a general and not in a technical sense as the part used for the purpose of travelling, and by the public. To him the case of "The Vestry of St. Mary, Islington v. Carrett (9 L. Rep. P. B. 278)," was conclusive. That case seems to have held this: In the Metropolitan Management Act, the expression new street is not confined to streets dedicated to the public. Held, that though the street may not have been dedicated to the public, it was a new street within the meaning of the 25th and 26th Victoria, chapter 102, section 112. The rule of Court, therefore, ordered that the judgment of the magistrate be reversed, and that the case be remitted to the magistrate, with the opinion of the Court, that the superintending architect had power to define the general line of buildings, though the place was not a highway dedicated to the public.

BREACH OF BUILDING ACT.—At Westminster, Mr. James Pullen Seagrave, of the Westminster Zinc Works, 46, Rochester-row, Westminster, was summoned last week by Mr. Edmund Drury, the district surveyor for St. Margaret and St. John, Westminster, for not giving two days' notice of his intention to erect a building at 13, Carey-street, Vincent-square, Westminster (18 and 19 Vic. cap. 122, sec. 41). He was also summoned under the 46th section for neglecting to inclose the building with walls of brick, stone, or other hard and incombustible substance (sec. 12, first schedule). The summonses related to a structure 20ft. by 15ft., on six iron pillars on wheels, with a vaulted roof, height from ground in centre 12ft. 6in. When first seen by the district surveyor it was not on wheels, but on stone bases let in the ground on concrete bottom, but was afterwards raised and put on wheels; it extended beyond the general line of front some distance, and about 3ft. above the height of the exterior wall of the premises. The magistrate had been to view the premises and the structure as it now was, and the district surveyor contended that it was a "building" within the meaning of the Building Act, and that under the 46th section the defendant, as the builder, was bound to inclose the building with incombustible material. The defendant said that whether on the bases alleged by the district surveyor or on wheels mattered little, for his contention was that in either sense it could not be a building; and when the surveyor saw it for the first time it certainly stood on the ground for the purposes of erection. Had it been erected originally on wheels it could not have been set properly square. He called it a "shelter" or "awning," and the Act under which he was summoned contemplated buildings—viz., structures, erections, or establishments, something permanent and fixed, but was silent as to what was a "building." He found by "Walker" that to build was to make a fabric or edifice on a foundation; that an "awning" was a covering spread over to keep out the weather; and that a "shelter" was something that covered from external injury, and this was all the alleged building was. It was moveable, and could be shipped from place to place, and was only intended to protect a brougham or two and a gig from the rain in the yard of Mr. Franks, the jobmaster, where it was situate. It had no sides or ends, and was never intended to have any, only a top, and if this were to be deemed to be a building, then the tents and awnings at the Horticultural-gardens, or the tarpaulin over a hayrick secured to poles well fastened in the ground must be buildings also. They were of combustible material, while his was a corrugated iron roof on iron pillars. Mr. D'Eyncourt agreed with the defendant that the Building Acts did not define a "building," but he took it that the Act was to be construed with regard to the surrounding circumstances of the cases brought under it. There could be little doubt that this was a "building" within the meaning of the Act, and had originally been intended to rest on the stone bases spoken of, but in order to evade the Act it had been placed on wheels. He had seen four or five men move it a little distance, but that, in his opinion, did not alter the case. From the holding in the case of "Stevens v. Gourley," reported in the *Law Journal Reports*, 1860, vol. 38, Part 2, "Cases at Common Law," he came to the conclusion that the present structure was a "building" within the meaning of the Act, and the defendant would be fined 1s. and 2s. costs on the first summons. With regard to the second, that was inapplicable; it was such a building that did not

require walls, and leave should have been asked of the Board of Works to build. The defendant asked what he was to do. His contract was completed, and the work done. Mr. D'Eyncourt said he had merely decided that it was a "building." Ultimately the second summons was adjourned for a month to enable the defendant to confer with the Board of Works on the matter. Mr. Seagrave produced his contract book to show that he had agreed to erect a portable corrugated iron roof to cover two or three carriages from the wet.

HOARDINGS.—At the Marylebone Police Court last week, Messrs. Langmead and Way, of 192, Gray's-inn-road, builders and contractors, were charged on a summons by Henry Tivy Tomkins, chief surveyor of Marylebone, with erecting and setting up at 119 and 120, Oxford-street, a certain board or fence for the purpose of depositing bricks or other materials in a manner not permitted by a certain licence granted by the vestry of Marylebone to them on May 16, 1879, whereby they had incurred a penalty of £5. Mr. Greenwell, vestry clerk, who prosecuted, said the defendants were employed by the owners of the premises, which were situate at the corner of Princes-street, to rebuild them. The defendants made application to the chief surveyor for permission to put up the proper hoarding, and a licence was granted by the officer to them to take up the pavement and erect a proper hoarding, the latter not to exceed 10ft. in height. There were also the usual stipulations as to a footpath, handrail, &c. The hoarding was erected soon afterwards, but instead of being 10ft. it was 25ft. in height. It consisted of wooden boards, which were covered by advertisements. The hoarding was also dangerous, as a high wind might blow it down. It was of the utmost importance in the public interest that the vestry should have the discretion as to what kinds of hoardings should be put up where the rebuilding of premises was going on. The rents received for hoardings to be used for the purpose of advertisements were sometimes so high that the builders or proprietors were induced to let the building go on slowly. For the defence it was contended that there was an unnecessary restriction in the licence, but Mr. D'Eyncourt pointed out that that should have been seen to at the time. After some further conversation, Mr. D'Eyncourt said the defendants had gone beyond the licence and had not shown the restrictions to be unreasonable. He should impose a penalty of £4 and 2s. costs.

CHIPS.

An organ, built by Messrs. Bevington and Sons, of Soho, was opened in Ulting Church, near Chelmsford, on Wednesday week. The case is of oak, and the front is decorated in gold and colours. A reredos is also about to be erected in this church.

The Guardians of Swansea have accepted the offer of Mr. S. Wyn, the contractor for the new block of buildings at the workhouse, to extend the same at either end, at an extra cost of £200, thus bringing the total amount of the accepted tender to £1,258.

The Town Council of Accrington decided on Monday to apply to the Local Government Board for sanction to borrow £89,000 for private improvements. The plans and sections for the proposed works have been prepared by Mr. Knowles, borough surveyor, and refer to 117 streets, having a total length of ten miles.

Our Office Table.

In the course of a lengthy description of the new offices of the Prudential Assurance Co., in Holborn, given with a good photo-lithograph of the building, the *Commercial World* gives details of the new pneumatic service of communication adopted in the building. In a central station, there are thirty-one pneumatic tubes, each terminating in a square receiver, having a slide in front, with a glass panel. The thirty-one tubes in this room correspond with the thirty-one divisions into which the business of the office is divided. Each one of these tubes is in direct communication with the chief clerk of the respective divisions. The secretary, say, desires information from department No. 1. He writes his requirement upon a sheet of paper, and, folding it, encloses it in a "carrier," which is a short metal cylinder fitting the pneumatic tube. Then, pressing a button, he signals to the operator in the central station that he desires him to receive a message. The operator, by means of an indicator, knows from which room or department the message is coming, and signals that he is ready to receive it. The secretary then places his "carrier" into the mouth of the tube, and does not further trouble himself until he sees the reply blown out of a tube and fall into a basket or receiver below. The operator now turns on a valve which connects the pneumatic tube from the secretary's room with the vacuum or exhaust chamber, when the ordinary pressure of the atmosphere acting upon the "carrier" at the other end of the tube, forces it almost instantaneously into the receiver at the central station. Taking the "carrier" he passes to the tube communicating with department No. 1. Drawing up the front of the receiver he inserts the "carrier," closes it again, and signals that a message is about to be sent. Immediately he turns the valve which connects the tube with the compressed air reservoir, and the message is instantly blown to its destination.

The date of the annual meeting of the Society for the Protection of Ancient Buildings has been altered from Thursday, June 26th, to the Saturday following, June 28th, at 3.30 p.m. at Willis's Rooms. At the last meeting of the Committee attention was called to the tower of the old church at Pinner, the top of which is to be rebuilt, and it was resolved that the church should be viewed and reported upon. We really think the Society may safely leave the architect under whose direction the work is being done at Pinner to mind his own business.

The buildings for the International Art Exhibition in the Crystal Palace at Munich, says a correspondent of *Galignani*, are rapidly approaching completion. The grand hall, a lofty apartment, 120ft. square and 70ft. in height, forms the central feature of the whole plan. The style of the hall is Renaissance. The decorative paintings in the domes and in the panels of the walls—allegorical tributes to the great masters

of all countries and of all ages, and emblematic of the various directions of art—are from the brushes of Professor Muller, Lindenschmitt, Wagner, and Spies, of Liezenmayer, Schraudolph, and Lossow. The four sides of this apartment open like triumphal arches into the adjoining halls, and the pediments of the great doorways are surmounted by colossal figures, dedicatory to all contributing nations. These are modelled by the sculptors Ungerer, Dennerlein, Ruhmann, Von Wahl, Professor Hess, Eberle, Hirt, and Ferd von Miller. The other halls and galleries, all intercommunicating, vary in their decorations, colour, and size; but all are of such extent that the 4,000 pictures and statues will have ample space. Towards the extreme right and left of the building are again two halls, higher than the other galleries—the one octagonal in form, with circular niches in the wall between the openings; the other oblong, with columns supporting a canopy, and each containing a fountain. These rooms are for the statuary. Other plastic works are distributed throughout the building. Architectural models, etchings, pencil and chalk drawings, as well as water-colour paintings, will be shown in rooms specially devoted to each. The international exhibitions are, in future, to take place every four years at Munich. The building within the Crystal Palace was, therefore, constructed in such a manner that it can be taken asunder in sections, and used again. About 4,000 contributions are expected.

A DEPUTATION from the Sanitary Institute of Great Britain waited upon the President of the Local Government Board, on Tuesday by appointment, to report as to the progress the Institute has made in the examinations of Local Surveyors and Inspectors of Nuisances. The deputation stated its wish that the President of the Local Government Board would send a delegate to a conference of the Council and other bodies, to be held at the Privy Seal Office, on Monday, June 16th, at 4 p.m., to meet the President of the Institute, His Grace the Duke of Northumberland, in order to confer on the subject of the examinations carried out by the Institute, and the appointment of visitors to the examinations. Mr. Selater Booth gave a most careful consideration to the various points submitted to him by the deputation, and promised that the subjects referred to him should receive every attention.

Mr. WILLIAM HAYWOOD, engineer and surveyor to the City of London Commissioners of Sewers, has reported to that body on the experiments with new gas lamps in Queen Victoria-street, made since March last, by and at the sole cost of the Gas Light and Coke Company. The burners are fitted with Sugg's London Argand governors and are of two sizes, consuming 22 and 50 cubic feet of gas per hour respectively. The smaller burners are placed in octagonal, the larger ones in dodecagonal lanterns. The 35 lamps replace 55 ordinary ones of 14 candle-power; the larger ones, five in number, are estimated at 200 candles photometric value, and the smaller ones, of which there are

Roofing Felts.—F. Braby & Co.

FITZROY WORKS, 356 TO 369, EUSTON ROAD, LONDON.
HATTON GARDEN, LIVERPOOL. GREAT CLYDE STREET, GLASGOW. AND AT CYPRUS.

30, at 80 candles. On these data the 35 experimental lamps should give 4.42 times as much light as the 55 ordinary lamps. (These statistics as to illuminating power are supplied, it may be borne in mind, by the gas company.) The expense to the Commission of the latter is £268 2s. 6d., and the actual cost of the improved lamps, according to the gas company, on an estimate based on the same schedule of charges, is £777 2s. 6d.—a proportion of 2.82 to 1. It follows that the general result of the experiment is to give nearly four and a half times as much light at nearly three times the cost. While the experiment demonstrates that the public ways can be lighted in an ample and satisfactory manner by gas, the question to be considered, says Mr. Haywood, is whether the public necessities are such as to render generally necessary a more expensive mode of street-lighting than that now ordinarily in use.

The Court of the Plumbers' Company recently appointed a committee, consisting of Mr. George Shaw, the Master; Mr. Digby Seymour, Q.C., and Mr. Philip Wilkinson, to consider and report as to the best practical means of extending the utility of the company and elevating the character and educational standard of the workmen engaged in the trade of plumbing. The committee, after an exhaustive inquiry, have recommended that any workman belonging to the trade who produces evidence of having been for fifteen years in good and approved employment as a plumber, and of having done his work to the satisfaction of his master, and who furnishes vouchers of good personal character, should be eligible for admission, free of expense, to the freedom of the company, with its privileges and benefits; and next, that any workman belonging to the trade who should produce a certificate of having worked for at least ten years as a plumber under one approved employer by whom he should be recommended for his skill, proficiency, and good character, should on passing an examination by the Court as to his knowledge of the principles and practice of the art of plumbing, be entitled to a diploma under the Company's seal testifying in the language of their ancient charter, dated in 1365, that he knows how well and lawfully to work and to do his work.

The Municipality of Florence have resolved to hold in November next a great "retrospective exhibition," which shall bring under public observation in the most representative manner possible all the portable art treasures of Tuscany from the remotest times down to the 17th century inclusive. The exhibition will be held in the Pitti Palace. It will include not only pictures, statues, drawings, ancient and modern coins and medals, intaglios, cameos, &c., but also paintings on glass, goldsmiths' work, glass, enamels, mosses, furniture, marquetry, wax models, ivory carving, objects in terra-cotta, enamelled pottery by Luca della Robbia, majolica ware, silks and velvets, brocades, carpets, and laces. There will also be musical instruments, books, manuscripts, bookbinders' work; finally, embroidered cushions, carriages, litters, painted cabinets, optical and other physical instruments, watches, snuffboxes, objects in niello—in fact, objects of every kind remarkable in the history of art. One thing only will be missed in this representative exhibition—the frescoes which since the 14th century have been painted so profusely in all the cities and little towns of Tuscany. But an effort will be made to remedy this blank. Sketches representing those frescoes, with inscriptions indicating the places where they are to be found, will be placed upon the walls, so as to remind the visitors of their existence. There will be Etruscan antiquities from Volterra, Cortona, Arezzo, Pisa, Fiesole, and other places. As to the middle ages, it is expected that a valuable collection will be exhibited; and Tuscany possesses such an amazing quantity of art treasures from the 14th, 15th, and 16th centuries, that it is not easy to imagine how even the spacious rooms and corridors of the Pitti Palace itself will be able to contain even a goodly selection of them.

At the meeting of the Leeds School Board on Thursday, the sites and buildings committee recommended that as the schools now in course of erection nearly complete the school provision required for the borough, the remuneration to the architect to the board for any schools hereafter to be commenced be by commission instead of a fixed salary.

CHIPS.

The War Office and Admiralty have just ordered a large number of a small but, as experience proves, a very useful and necessary article in tropical climates—Atkins's charcoal pocket-filter—for shipment to the Cape for the use of the troops.

A Paris despatch states that the chief prizes of the Salon were awarded on Thursday week. The prix du Salon, 4,000 francs per annum for three years of foreign studies, goes to M. Flameng for his picture of the Girondins in prison, and the two honorary medals to M. Carolus Duran for two portraits, and M. de St. Marcieux for his sculpture, "Génie gardant le Secret de la Tombe."

The foundation-stone of a new Calvinistic Methodist chapel was held at Penygroes, eight miles from Llandilo, one day last week. It will seat 275 persons, and is to be completed by December 1st. Messrs. B. and E. Jenkins are the contractors.

The Stratford-on-Avon, Evesham, and Redditch Junction Railway was opened for traffic on Wednesday week. It continues the east and west junction system from Stratford to Broom, a distance of 7½ miles, where it joins the Midland Railway, and thus puts that system in direct communication with the Great Western and North Western systems. The new line was commenced about two years ago, the contractors being Messrs. Liddell and Barkley, who sublet the work in two sections, and the engineer is Mr. T. F. Burke, of Stratford. All the works are of substantial description, the bridges being solidly constructed of stone.

A stained glass window has just been placed in St. Mary's parish church, Dover. The subjects are, "The Presentation in the Temple," "Jesus Working as a Carpenter," "The Last Supper," and "The Crucifixion."

A new vicarage is about to be built at Rolvenden, East Kent, the tender of Mr. J. W. Bingham, of Headcorn, having been accepted for the work. Messrs. S. and A. Smith, of Hastings, are the architects.

At a meeting of the Southport Town Council on Tuesday evening, the tender of Messrs. Gripper and Bayliss, of Nottingham, to construct the promenade extension works in section No. 1 for the sum of £20,752, was accepted. It was also decided that the works comprised in section No. 2, for £10,410, should be offered to them. A large number of tenders were sent in—from Manchester, Liverpool, Leeds, Bradford, St. Helens, and other places.

A chancel organ was opened in the parish church of Alburgh, Norfolk, on the 30th ult. It was constructed by Messrs. Morten and Taylor, of Regent's Park. The case is of oak, panelled and stop-chamfered, with moulded angle posts, and has been designed by Mr. C. H. Lohr, of London. The pipes are displayed on three sides, and are of spotted metal, burnished in the Continental fashion.

The parish church of Burnham, Essex, is undergoing further restoration by the erection of 7 new windows in the chancel, at the expense of Sir Henry St. John Mildmay. The work is being executed by Mr. Charles Read, of Burnham.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Architectural Association. Dinner at Holborn Restaurant.

WEDNESDAY.—Society of Arts' Conversazione at South Kensington Museum.

British Archaeological Association. Papers on "Discovery of Roman Remains at Hampstead Norris," by W. Money, F.S.A.; "Coronation Medals of George II. by German Artists," by G. G. Adams, F.S.A.; and "Inscribed Stones on Ely Cathedral," by W. de Grey Birch, F.R.S.L., 8 p.m.

HELLIWELL'S Patented NEW SYSTEM

IMPERISHABLE GLAZING WITHOUT PUTTY. All Woodwork is covered, and no outside Painting is required. Old Roofs Re-glazed. Any one can repair or take in pieces.

See half-page Advt. in next Number.
T. W. HELLIWELL, Brighouse, Yorkshire;
or, 19, Parliament-street, London.—[ADVT.]

Trade News.

WAGES MOVEMENT.

ARBROATH.—Notices having been posted in the workshops of Arbroath that after the 9th of June the hours would be 54 instead of 51 per week, the operative joiners have come out on strike against the movement. This is the first attempt to extend the hours of labour in the building trade in Scotland, and the result is looked for with much interest.

J. & E. HALL

(ESTABLISHED 1785),

ENGINEERS, MILLWRIGHTS,

FOUNDERS, AND BOILER MAKERS,

Works:—DARTFORD, KENT.

London Offices—21, St. Swithin's-lane, E.C.

Sole Makers of MOTTE'S

UNIVERSAL CRUSHER.

THE SIMPLE PESTLE AND MORTAR ADAPTED AS A MACHINE.

Hand and power Machines with Mortars, of from 6in. to 30in. diameter.

These Crushers are the most effective and economical Machines known for reducing the hardest materials, as Emery, Granite, Quartz, Glass, Flints, Cement Clinkers, Pyrites, and the like, from any size down to the finest powder. They will also be found very useful in a Laboratory for grinding, bruising, or mixing drugs and colours of every description. The facility with which these Machines are regulated to deliver the ground material, now at one size and then at another, forms one of its chief attractions.

PRICES AND ALL PARTICULARS UPON APPLICATION.

HART'S PATENT

CYCLIC ELEVATOR.

For which see Advertisement each alternate insertion.

EDGE-RUNNER MORTAR MILLS, In specially hard Cast Iron, outlasting several of the ordinary description.

ESTIMATES FURNISHED FOR

CEMENT & BRICKWORKS MACHINERY.

Complete with the latest improvements, together with the best practice for laying out the works for strict economy.

ENGINES, BOILERS, CASTINGS, AND ENGINEERS' WORK IN GENERAL.

THE BUILDING NEWS.

LONDON, FRIDAY, JUNE 20, 1879.

HISTORICAL WINDOW-MAKING.

IN all ages and countries, where the climate has not allowed of hypæthral, or sky-open temples and other edifices, the window has been regarded as a most important part of the structure—next even to the door itself. It happens just now, however, that an Italian society of architects is engaged in discussing the question both of knowledge and of taste possessed by different generations of builders in this respect. The illustrations brought together are certainly interesting, from the Florentine, or purely Italian, point of view; but they are, to a disappointing extent, local, traditional, and narrow, leaving out of sight, indeed, those examples—which no student of the subject should omit—which adorn the shrines of Constantinople, the old English cathedrals, the châteaux of mediæval France, the mansions of modern Paris, and even the old churches of Berch-sur-Mer, Narbonne, and Toulouse. With respect to the structures at Constantinople, the first question raised was with respect to the position of the windows in the dome—an important matter, and one long discussed. In the result, in St. Sophia, there were introduced, in the mighty cupola, a number of small glazed archways, clustered close together, beneath the higher-springing pillars, producing a light so vivid that it seemed to separate the dome from the rest of the church, and this was considered a triumphant effect at the time. As to the use of windows in the Byzantine “*narthex*,” a difference of opinion and custom arose. Authorities varied as to whether the “*narthex*” should be regarded as simply an open portico in front of the nave, or an auxiliary roofed inclosure, similar to those at Cluny and Vézelay, though, undoubtedly, the earlier specimens were unroofed and unwallled, and had, therefore, no need of windows. We find, in fact, a transition from this style in the grated doors and cell-like apertures, encircled by masonry, which belong to the “*drum-headed*” churches of Constantinople, long after the consecration of St. Sophia, and which, it is affirmed, were, at a far later period, imitated in the chapels of Alnwick, in Northumberland, where the windows, in troublesome days, were always taken out of their frames and laid by, in expectation of more peaceful times. It was some such feeling, perhaps, that induced the architects of the fourteenth century to recommend that window-frames, for national edifices should, for the future, be constructed in iron, as was done in the case of St. Germain l’Auxerrois, at Paris, in which the masses of metal and of masonry employed were nearly equivalent. Upon a comparison of cost being made, however, the result was in favour of stone, and stone, therefore, was thenceforth employed. This latter point, moreover, was brought into salience by a curious memoir on “*military*,” or “*murderous*” windows, as they were styled, belonging clearly to the Middle Ages of war and intestine feud. One is a small square, another oblong. This takes the shape of an elongated slit, that of a narrow cross. The cross form, indeed, is frequently repeated, with variations of detail. Yet none of these light or loop-holes can be described as windows, in the proper sense of the term. They were simply apertures, serving as means of war, like those in the White Tower of London. Such, indeed, to a great extent,

were nearly all these constructions, until the builders of the Middle-Age churches perceived that they wanted something more than mere arrow-slits, and designed their arcade, “*bull’s-eye*,” right angle, basket, apsis, façade, and lateral wall windows, which, however, had had their natural predecessors long before. It was then asserted that the mason had too much of the work assigned him, and the glazier too little; but the discussion, at any rate, brought about some useful historical criticism—upon the Roman windows—simple bays, pierced in the surface wall, with frames of specially sculptured stone, and almost invariably arched, whether with columnar side-supports or not. It is a common mistake, however, to suppose that the horse-shoe window was a purely Saracenic invention; any more than the “*bull’s-eye*” was exclusively French. We have illustrations of all these styles, borrowed from various sources, at Ecouen, where the window expands into a vast field for the artist’s powers to work upon; at Beauvais, where the window seems like a door, richly illuminated by art to admit the light of nature; and at Arles, where it simply suggests the idea of one deep, struggling gloom confronting another. It is about this period that we find a wonderful commingling of fancies in window architecture—wheels, roses, stars, interlacings of arches, all well-known, of course to the chroniclers of the art, but, nevertheless, often too drily studied to be of popular or general utility. Yet, among them, few, perhaps, are more remarkable than the circumstances noted among the “*Histories and Researches of Sanval*,” who writes, in 1698, “*Dr. Martin Lister showed us over his hotel, which has large sash windows, which were made from a model that he had received from England, the method of counterbalancing the sash being at that time unknown or not in use in France.*” Nor has it been ever admitted; and France, singularly enough, is, in this matter, precisely as far behind the rest of the world as it was when Sterne wrote his “*Sentimental Journey*,” opened a window, and was not able to shut it. Indeed, this question of how to close windows, in churches especially, became an affair once of serious practical argument. Next to doors, clocks, and bells (says a monastic report of the fifteenth century), is the importance of window-fastening in churches. But this, of course, was an incidental subject. It is more interesting to consider what were the numbers, dimensions, and forms of these light-giving arrangements in the ancient or rather the older basilicas of Europe. In this inquiry we are very much helped by M. Alb. Lenoir’s “*Treatise on Monastic Architecture*.” He says that the windows of the earliest monastic churches were simply long openings in the walls, terminated at the top by an arch, and occasionally surmounted by a round aperture, covered in with glass and called an *oculus*, as, for instance, in St. Paul’s at Rome, though, apart from either pagan or Christian theory, the facts remain that there are 120 windows in St. Paul’s Cathedral, 80 in that of “*St. Peter of the Vatican*”—on a larger scale, however—and 102 in the Fane of Saint-Martin, erected by Perpetuas, who boasted that, for every door in the structure he had provided two windows, “*with movable blinds of marble.*” A very striking illustration of this is mentioned by M. Cæsar Daly, who found, in Brittany, fourteen years ago, a window, shaded by a stone cover, and protected also by iron bars, arranged cross-wise. Not very dissimilar is one belonging to the Guadagna Palace, near Palermo, a perfect specimen of Middle Age art, mingled with a little of the spirit of the Renaissance, as these influences grew up in Sicily. The palace itself is remarkable, being constructed of a perfectly black stone, encrusted with a kind of agate, after the fashion, somewhat, of the old castles and châteaux in

Auvergne, and the ecclesiastical edifices in that province even, amongst which the Cathedral of Puy to the eye of every tourist so prominently stands out. This window is “*bratised*” in a wall of plain masonry; it is enclosed within one pointed and two smaller but similar arches, divided by a spiral column, with elaborate decorations in a sort of platter-pattern, so to speak, on either side, very unlike the adornments of that which it was long agreed to term the Roman window; the rose, for instance, of which so lovely an illustration occurs in the church of Santa-Maria, at Toscanella, and of which we find hints in the celebrated “*Seals of Norwich*,” and the missal of Boxgrave, though the Roman fashion was, as a rule, to introduce an arch in the summit, even if it were of smaller dimensions than would be warranted by the lower parts of the work. The Latins and the Byzantines usually protected their windows by trellises, so to call them, of marble or of stone; but Gregory, of Tours, informs us that in France the custom commenced early of substituting for these materials simple wood, after which white and transparent glass began to take the place of all three, as elsewhere it had done indeed in a ruder Roman period. In the ninth century the church windows were filled with coloured glass, and in 1052 those of Saint Beniqué, at Dijon, representing the martyrdom of the patron, were described as pictures glowing with the holiness and the blood of martyrs. England, Sweden, and Denmark, at about the same date, bethought themselves of glazing in their ecclesiastical edifices, so long exposed to the merciless visitations of wind and weather; but, in spite of this, the windows of the Abbey of Jumièges long remained a marvel in Europe—an archaeological discovery, indeed. Its windows were the principal wonders of the edifice; they were pierced in the walls of the triple arcade at a great height from the ground, formed into the shape of leaves and Corinthian capitals, turned here into an Arab and there into an Oriental pattern, divided by pillars, yet united by long sweeps of harmonious decoration, and, reaching to the roof, were probably continued through it, a problem, however, which the most zealous archaeologists have not hitherto been enabled to solve. Nor has it been determined, with any approximation to certitude, whether they were, in either the ancient or the modern fashion, glazed or not, though it is interesting to note how, in the history of this subject, as substitutes for glazing, for the protection of windows in both religious and domestic use, so much care was bestowed on balconies and verandahs, as in Switzerland and Sweden, at Amboise and Baden—metal canopies and other contrivances for keeping out the wind and the rain, some of them undoubtedly characteristic and picturesque, but, for the great part, disfiguring and inharmonious. The history, by itself, of these attempts at preserving the architectural character of windows, without retaining them in their inclemency wherever chill climates demanded shelter, would be a chronicle of singular variety. Another stage is reached when we find fixed windows so oppressive to the frequenters or inmates of public or private edifices that the necessity of ventilators is insisted upon, as, in the fifteenth century at Caen, in the sixteenth, at Saint-Germain, near Paris, and even earlier, as the Italian Society reminds us, at Genzano, in the kingdom of Naples. There is a singular specimen of this novelty—as it was then regarded—in the “*Hospital of the Three Nurses*” at Narbonne, so named without any assignable reason, because every visitor to that city will have perceived that there are five figures of nurses, apparently, instead of three, sculptured over the principal doorway. It would seem, however, that here was tried, at a very early date, the experi-

ment of doubly-glazed, or doubly-shuttered, windows for infirmaries. They are totally dissimilar from what were termed the square "leathern" windows, dating so far back, in France, as the reign of the thirteenth Louis, which were supposed to exclude unwholesome or vitiating air from the galleries—as they were then termed—of hospitals and the chambers of palaces, and which were imitated, though in a coarse manner, throughout the latter half of the sixteenth century, when the "mezzanine" window came into vogue, and served so many social purposes, far less respectable than those of the *Napoleon Hospital at Berch-sur-Mer*, already spoken of, in the *Pas-de-Calais*, about thirty miles to the south of Boulogne, where the window is made a matter of the highest importance, and is styled "the guillotine," being tall and narrow, and, as the local architects declare, the nearest approach to the English system that can be conceived. Their idea is, that the whole of the space can be "aerated" above and below, by a simple and immediate shifting of sashes, almost in a moment, though, even at *Berch-sur-Mer*, the principles of compensating weights is not admitted. A point of interest is, whether through the various periods of history belonging, even apart from glass, to this most beautiful feature in architectural art, its full and perfect meaning was entertained. We cannot think otherwise, small as has been the attention given, either historically or critically, to the subject. For although, in architectural manuals, and other works of a similar class, the subject of windows, considered apart from their glazing, is, in a general sense, almost passed over; still the great builders must have met with many of their utmost difficulties, as they certainly achieved some among their mightiest triumphs, upon this path, which leads, no doubt, to high and to low, and involves many questions appertaining to higher interests than those consulted by *M. de Cambaceres* when he first drove in a carriage with glazed windows through the streets of Paris. These, however, are the mere filterings of a topic which has, in fact, a history and an antiquarianism of its own quite deserving of a place on a level with many others, upon which more may have been expended. It will be evident why, taking this point of view, we have left out of notice the glass-painting art and window restorations of the present day.

COMPETITION DESIGNS FOR THE WESLEYAN THEOLOGICAL INSTITUTE, NEAR BIRMINGHAM.

THE designs for the Wesleyan College, at Handsworth, now on view at the Wesleyan Centenary Hall, in Bishopsgate-street, present two distinct types of arrangement, while the exterior elevations are mainly in two varieties of style—Gothic and Renaissance. Mr. Waterhouse's selection, in the main, must be generally regarded as satisfactory, though it is certainly rather disappointing to find some very excellent and skilful designs in the cold shade. Mr. Waterhouse adds to his report the reasons that have influenced him in coming to a decision upon the forty-two designs. They are: "1st, their general adherence to the conditions, and especially to that of cost; 2nd, their general excellence, fitness for the special objects of the college, and for the site with its peculiarities of contour and aspect; 3rd, the evidence evinced by the drawings of their authors being skilful constructors and artists, and of their ability to carry out the work in a satisfactory way if confided to their care. I am well aware that it is rare indeed to find any one design pre-eminent in all these respects, and I do not pretend to have done so in the present instance. There is not a design in the room probably that you would wish to see carried

out without some modification. I must, however, compliment many of the competitors on the excellence of their work, which seems to me far above the average." The three designs which have been placed first by Mr. Waterhouse are "*Ut Migraturus Habita*," by Messrs. Ball and Goddard, of Birmingham; "*Wesleyan*," by Mr. C. O. Ellison, Liverpool; and "*Speramus*," by Messrs. F. and A. Wheelton, Birmingham, and H. Beck, London. The committee have unanimously chosen Messrs. Ball and Goddard to be the architects of the new college. The conditions required a building to accommodate seventy students, each to have a separate study and bed-room not less than 10ft. square, two rooms for assistant-tutor, a dining-hall, lecture-hall, six small lecture and class-rooms, library, professor's retiring-room and domestic offices, &c. A governor's house, with separate entrance, and two detached houses for professors, were to be provided. The buildings were to be plain, of brick, and the cost, including roads and fencing, not to exceed £23,000. The authors of the three have adopted a long front building, with transverse blocks, more or less pronounced, thrown out either in the rear or crossing the main line of building, and this seems to be the most commonly accepted block arrangement; while another class of designs adopt a quadrangular disposition, having one or more open quadrangles or courts in the centre. "*Ut Migraturus Habita*," is in a Late Gothic style, in red-brick and terracotta—two materials in which the referee has had, perhaps, more experience than any other living architect. Taking the plan, we are bound to admit its merits. It is U shaped in the distribution of the blocks. There is a centre entrance leading to a longitudinal corridor of considerable width at the back, lighted from the side courts behind. There is a wide arched hall with a lecture-room 48ft. by 30ft. in front, at both ends of which corridors give access to the class-rooms. Thus, the teaching block, with professors' rooms each side of entrance, occupies the central part of the plan, and is well located; the long lateral wings being divided into students' rooms and dormitories above. The library forms an advancing wing on the north-east angle, balanced by the governor's house at the other end of the façade, behind which and extended westward is the kitchen—court, and offices, the most unsatisfactory part of the planning. The studies are 10ft. square and extend along the front and through the north-east and south-west wings. At the extreme end of these wings are the latrines. On the first floor the same arrangement exists, excepting that the lecture-room and class-rooms are not carried up. The corridors are 8ft. and 7ft. wide, and those traversing the side wings are lighted by centre windows into the respective courts. The windows are in single and double lights, with flat-pointed heads under labels. The dining-hall, 48ft. by 30ft., at the south-west inner angle, is well placed for communication with the domestic offices, and is groined in four bays. The front hall, we find, is not dark, as in many other cases; it is lighted on each side of the lecture-hall block, and its centre also obtains light through the roof of the corridor which is kept low, between the vestibule and the lecture-room, while the latter is lighted on the south side by windows. The composition has been treated externally in a dignified and collegiate manner; a bold and massive tower, of good proportions, emphasises the entrance, while the bay window and gable end of library, and the governor's house, produce a well-balanced effect. The detail is also good, there are no extravagant or excessively-carved features; and the well-finished line and tinted elevations do ample justice to the design. "*Wesleyan*" is clever in detail, but more pretentious, unquiet and restless in style. We certainly

prefer the alternative lower elevation as more suitable and dignified than the modish semi-domestic treatment in the upper one, broken up by gables in pairs in a half-timbered style. The centre tower has an open pent roof, and rises out of a hipped roof of unpleasant proportions. The admirable sepia drawings are all cut round and mounted on toned paper. In the plan we observe a careful distribution of the main and teaching blocks, the corridors traverse the centre of each block, intersect, and are lighted at the ends; the class-rooms, library, and lecture-hall form an end block in the rear approached by a central corridor from the main entrance, 15ft. wide. The class-rooms are on the left, and the library and lecture-hall on the right side of this corridor. The domestic offices form the south-western block, and are inconveniently close to the dining-hall, which is placed between the kitchen and master's house. The tutors' rooms are obtained at the angles of the front block. The studies and bed-rooms have angle fire-places. We observe on the first floor the centre buildings are roofed low, and the corridors have lantern lights, and the access is by staircases at the angles of side wings and at end of east wing.

"*Speramus*" has certainly less to commend it as an elevation than some other designs. It is neither Gothic nor Classic in inspiration, though it has semi-Gothic features, and is commendable at least in its common-sense plainness. The towers or rather lanterns over the halls in the wings are heavy and unmeaning, and if they are intended to transmit light to the corridors they are certainly unnecessary; the centre treatment of bays and flat gables to the library and lecture-hall is unsatisfactory, while the lowness of this part, it being roofed back to the middle corridor, is unfortunate in the general grouping. On the other hand, the design has some good points in the planning. The main block has the lecture-hall and rooms made a prominent feature of in the front elevation; the central block, in fact, is devoted to the educational department, while the wings and return blocks, which latter cross at the ends, are given up to the students' rooms; these are 12ft. by 9ft. each, and ranged on each side of central corridors, and have angle fire-places. The corridors are lighted at the ends, and halls are shown at the junction of the long and end blocks which have the lanterns we have mentioned above. Another good feature in the plan is the central position of the kitchen offices behind; these are connected by a corridor with the main block. The master's house is at the west end joined by a passage to the wing. On the first floor the centre part is occupied by the housekeeper's, sick, and convalescent rooms behind corridor. With the exception of the ill-lighted corridors in the centre, the plan is economical, and the position of the domestic offices facilitates the working of the establishment. One very excellent design has scarcely met with the position its inherent merits deserve; we allude to "*Epworth*," the authorship of which is at once apparent to us as Mr. J. M. Brydon's work. It is well drawn, thoroughly artistic in spirit, in Late Gothic, of the scholastic type of which we have some noted examples at Oxford. The drawings are boldly, but heavily tinted, and display the hand of a true interpreter of the style. The front elevation has a massive square tower, with open stone traceried finish to the angle turrets in the centre marking the entrance, while the lecture-hall and library, class-rooms, and governor's house contribute to give an importance to the front that has been overlooked in all the three selected arrangements. The dining-hall placed at the back, with its bay recess and fleche, and the quadrangle elevation of front block are charmingly treated. Turning to the plan we find an inclosed square or quadrangle.

The teaching apartments, class-rooms, &c., form the main front block, the dining-hall projects into the quadrangle from the centre of the rear block, and the kitchen offices are well disposed of behind in a separate building connected to the last-named block by a passage. Centre corridors traverse the four main blocks, and are lighted at the ends, while the front corridor is lighted from the central area. The lecture-hall and library have bold square bays in front. It will thus be observed that the educational and domestic offices are central, and well placed as regards the students' rooms, which occupy the sides of the quadrangle. Below it we observe another design, "Centralisation" (Mr. H. W. Pratt), in which Gothic has been treated with success. Here, also, the library and lecture-room are made to play an important rôle in the design, though the division of the plan into two garden courts is undesirable, and the plan, clever in its administrative departments, is complex. "Lux et Aër" is a neat set of drawings in Gothic of some merit; the plan is symmetric, and consists of a double square, the hall and library being in front, with two quads, centre lecture-rooms, and dining-hall with kitchen offices behind, and forming a projecting block in the centre. A connecting corridor joins the large lecture-hall and library with the return-blocks, and these are of a plan with inverted outer angles. "Che Sara Sara," although it fails in plan, is one of the most unaffected and artistically-conceived elevations. It is in a quiet, Domestic Gothic style, but with a decided foreign flavour, reminding us much of Mr. Street's work. A charmingly simple octagon-fronted tower, terminating with a low roof (forming the internal staircase) flanks the entrance, while a row of gabled windows break the elevation. The corridors are imperfectly lighted, though skylights are marked at intervals; the dining-hall and lecture-room form a middle cross-block, and are both lighted from the roof. The domestic offices are placed in a distinct parallel block in the rear, making altogether four small open courts for light and air. The drawings indicate much feeling, and are tinted in a light but effective manner. "Proportion" in a triangle is a clever but over-elaborated plan, we believe by Mr. C. H. Driver. Its block arrangement consists of two elongated quadrangles, comprising four garden courts, which light outer corridors. The lecture-hall is central, opposite the entrance; the dining-hall and kitchen, also upon the same axis, have side corridor approaches, while the lecture and class-rooms and library are placed in front. The students' quarters occupy the blocks surrounding the courts, and the domestic department form the rear block. The author has well separated the educational from the domestic part, and the corridors receive direct light from the courts. Obviously the objection to this plan is that a large area is covered and long corridors are required. The elevations are Renaissance in character, broken by dormers emphasised by a central and lateral towers. "Quis" (Messrs. Tarring and Wilkinson, of Basinghall-street) is the motto of a carefully-prepared set, in which a 2nd floor is obtained. The plan consists of one main block behind, with two projecting wings at the end of it, and an advanced parallel block for the teaching-rooms and staff in front, connected by a centre corridor to the main building. The students are confined to the long block in the rear, the dining-hall is separated by a short corridor from the east wing, with the kitchen offices in the rear, while on the west side, quite detached, is the governor's house. East and west quads are obtained in the front, the main stairs are placed in a large hall at the junction of the cloister-approach with the front block, and the long corridor to the students' block is lighted at its ends.

For separation of the domestic and teaching departments the arrangement is a good one, and the stairs are central. Gothic of the 14th century is adopted, the groups are well broken, and though the detail of it here and there lacks scale (as in the turret), the design is in advance of many others in the style. Near this design we come to another in a species of Gothic now only known in old books of the style, and the work of forty years ago. "Res non Verba" is an expensively prepared set of plans on the long and three cross block system; the kitchen and dining-hall are in the centre block behind, and the lecture-hall an advanced building in front of the main students' block; but the plan is all breaks, and the author has shown as much unnecessary trouble to light his long corridor by gaps as others have neglected it. "Fleur de Lis" is the motto of another design of the conventional type. In this case the domestic offices form the west block or wing, with the dining-hall in the inner angle of it with the main block; the lecture-hall forms a corresponding building on the eastern angle. We cannot quite understand how the corridors are lighted, though there are courts for light at the junction with the extreme wings. On the upper floor the two halls are roofed, and the sick-rooms are obtained in the second floor of the centre portion of main block. A Late Tudor, with a centre square tower over the entrance, with an oriel of two stories and dormers along the front, are the chief features; but the three-story middle portion of the façade is heavy, and the whole is in a somewhat used-up phase of a costly style. "Ars et Labor" is a quadrangular arrangement with open centre area; the blocks intersect and have corridors lighted at the ends with four angle stairs. The library faces the entrance in centre, the kitchen and dining-hall are located in the rear block, and the master's house at south-west corner. One objection is that the lecture-room is over dining-hall. The design is in a bold Gothic, with a low tower, and dignified in general grouping; the wings are pronounced by gables and oriels, but the teaching and domestic arrangements are not well separated. "Suitability" is long and straggling, with four advancing wings in a feeble Gothic; "Health" is of the usual  shape, the corridors are lighted by octagon halls placed in the main block, which have the effect of breaking up the composition, and giving a very fragmentary effect to it—Gothic of a Late kind, good in detail, but rather effete, is adopted. "Experience" is undoubtedly clever in general design; the lecture-rooms are in a block behind, approached by a centre corridor; the domestic department and master's house form a rather confused west wing, the residential in front and east wing. The long passages in the domestic part are objectionable. Gothic of a Fourteenth Century type is chosen for one of the designs; the windows are pointed and traceried, and the gables and turrets costly. Scheme B shows a quadrangular arrangement, treated in a Perpendicular style with centre tower. "Fiat Justitia Ruat Cælum," is an extravagant proposal in four transverse blocks, leading from a front building; an alternative design shows a vast semicircular block with an inner corridor for students, and a lecture-room in the centre. "Wesley" is extravagant in its distribution; the lecture-hall and library are on either side of entrance, there is a lofty tower in the centre, but the roof is monotonous. "Comme il Faut" adopts a quadrangle arrangement and makes the lecture-hall the centre feature projecting into it; the dining-hall is in front, and is made a feature in elevation which is Renaissance, with centre tower, neatly drawn. "I look upon all the World as My Parish," is square with a quadrangle in centre; the library and dining-

hall are placed along front. The elevations are Late Gothic in dress, with pointed windows above, and central tower and oriel, clever in drawing. We prefer the back elevation. "Fides" is symmetrical, forms a double quadrangle with dining-hall and lecture-hall in centre, and class-rooms in front. The style is round-arched Gothic, heavy in grouping and disconnected. We can only name a few others which have lost sight of the conditions as to cost and economy. "Faith," shown in a crudely-coloured set of plans, adopts the usual plan; the domestic part is curiously articulated at the angles, with glazed doors for lights, Queen Anne in style with lofty tower. "Thanksgiving" is a neat set, but ill-considered in plan, Gothic in elevation. "Pense à Bien" is ill-disposed in a heavy Gothic; "X and Y" look like a row of ordinary houses, with no pretence to character in style, a quadrangle in plan; "Sperabimus" is the same in arrangement, Elizabethan in style. We may mention also: "Auxilio Divino," "Wesleyan," "N in Circle," "Air and Light," "Tenez," "Faith," "Economy," "Cross in Circle," "Spes," "Convenience," "Suitability," "In Due Season," &c., as other designs in which the authors have shown considerable care and skill, but little or no adaptation of plan to meet requirements, while in architectural design they have exceeded the limits of cost, or fallen below the standard of style. As will be observed, Gothic preponderates; there are only one or two attempts at Queen Anne, and a visitor might almost assume, but for the effete phaso chosen by a large number of the competitors, that the first-named style was the prevailing one. For collegiate buildings, undoubtedly, Late Gothic has many claims; it is the style almost consecrated by three centuries of use in our great educational centres, and, perhaps, no phase of Renaissance could be found so suited; but it is an expensive style, and the authorities have done wisely to select a design in which the simplest and most workable features of it have been employed, with a view to the materials suggested for the construction of the building.

THE INTERNATIONAL AGRICULTURAL EXHIBITION AT KILBURN.

CONSIDERABLE progress has been made at Kilburn in the preparatory works for the forthcoming Exhibition, the largest of the kind the Royal Agricultural Society has ever held. The site comprises upwards of 100 acres of land: between the North London Railway on the north and the North-Western Railway on the south, being bounded on the west side by Salusbury-road. Two railway stations are in immediate proximity to the ground, one being the new station of the last-named road on the London and North-Western, in course of construction, and the other Kensal Green Station on the North London Railway. Between these two lines the plot of land forms a level area of trapezoidal shape, and until recently drained was in a waterlogged condition; it is now drained and covered by cattle and implement sheds, arranged in rows between avenues. We have paid a visit to the exhibition site, and can give our readers some idea of the works and erections now being pushed on with ceaseless activity for the show, which is advertised to be opened to the public on the 30th of the present month. Entering the show ground, we find that the sheds and standings have been arranged chiefly in parallel rows running east and west, and these are crossed by a central avenue of nearly 300ft. wide, in a north and south direction, besides another narrower avenue from the Salusbury-road entrance running in the other direction. These cross entrance roads leave four unequal groups of sheds. Those on the east side of

the chief railway entrance are implement-sheds, of which there are 6 parallel rows, each row of about a dozen sheds. The cattle and sheep are to be located in rows of similarly constructed sheds on the west side of main avenue. Walking through between the rows of these erections we notice that the implement sheds are 20ft. wide, with about a space of the same distance between them, and constructed of posts 3½ in. by 3 in. and 7 in. by 3 in. at the angles. The posts are held together at the top by ties strengthened by pieces of flat bar-iron. The rafters are placed one above each upright and one between, and spiked down to the plate, and they are tied by a collar; the framing thus constructed will be covered with canvas. The sheds for machinery in motion occupy the north and south sides of the ground, and are several hundred feet in length. Each shed is 25ft. wide, with a space of 15ft. to 20ft. apart. The uprights are stouter, and the main rafters are cross-braced, and the whole of the timbers are put together by bed-bolts. The sheds are canvas-covered, the canvas being supplied by Mr. Unite, of Edgware-road. The boundary of the site on the east and return ends is surrounded by stands for seeds and models. These are of uprights covered on the sides with weather boarding. The roof is felted. One of the main entrances, composed of a structure of a more finished and durable character, forms the centre of the eastern boundary along Salusbury-road. It is a long low range of wooden buildings of architectural pretensions, with a clock-turret in the centre, adorned by a pediment, and supported by raupis. The clock has been provided by J. Bennett. A row of turnstiles occupies the centre, while the ends have pedimented wings for official and other uses. Exactly opposite this entrance is one of the main avenues we have mentioned, about 100ft. in width, and from this point to the Kensal-green entrance a steam passenger tramway is forming, which will convey visitors from one end of the show grounds to the other. The tram will be worked by Messrs. Fowler, of Leeds, who have adopted a 2ft. gauge. Passing up this avenue a few hundred yards, we arrive at the junction of the main avenue, and on our right in the wide open space we see a large timber building with a projecting clock-tower in front, which is intended as the members' club. It is certainly the most architectural erection in the whole ground, its clock-tower forming a centre object from the railway entrance facing the main avenue. The main structure is rectangular, constructed with louver boarding along the top and weather boarded. It is of considerable width, and has braced principals, and the interior is fitted with rows of tables and seats. The tower, however, has the greater claim to notice. Constructed of wrought timbering, it rises to a height of 60 or 70ft., and is framed with timbers in stages which cross at the angles and project. The upper story of the tower is tastefully finished; the horizontal timbers protrude at the corners and form ornamental brackets, which carry small pillars of wood supporting the projecting eaves of the roof. Mr. G. Hunt, of Evesham and Regent-street, the surveyor to the Society, was the architect of this building, and we believe the clock will be supplied by Mr. Benson. Turning from the clubhouse southwards and proceeding up the avenue, we notice another ornamental structure of wood on a cruciform plan, the ends of which are finished polygonally and hipped, and having widely projecting rafters, supported by cut brackets painted of a red colour. This is called the "bodega," where Spanish wines will be sold. Like the last, it is constructed of wrought timbers, panelled below with arched sash-lights, and is surrounded by a counter for the supply of refreshments. In the centre of the long wings are tables. The structure is painted in too

garish and ill-assorted colours—a bright red and a yellow or buff. Other erections or refreshment saloons are in progress, and the main avenue has already a particularly busy and gala appearance, which will be increased as the implements, cattle, and other exhibits arrive. We think something might have been done to make these central vistas of the show a little more artistic. The open space it affords for exhibits of all kinds might be utilised in other ways than by refreshment saloons. On each side model cottages for labourers, large models of agricultural buildings, conservatories, and garden accessories might be arranged with considerable effect, and the great show on the Champ de Mars be repeated in a more modest way. There are hundreds of manufacturers who would have gladly contributed exhibits of this kind to show if they had known they would be granted one of the main approaches. Greenhouse buildings, stables and their fittings, iron park-gates, zinc roofing, concrete construction, and building materials and appliances, sanitary improvements generally, are clearly within the scope of a great agricultural exhibition, and we shall be surprised if these are not represented largely at the forthcoming show. We are glad at least to find that one of the buildings in the main avenue is to be used for the exhibition of designs and models for farmsteadings, and fittings on a large scale, and we believe one of the undoubted benefits this society can confer would be the promotion of competitions for the improvement of farm buildings. We may justly expect to see the results of the experience of other nations in these exhibitions not confined to agricultural implements and mechanical improvements merely, but extended to architectural efforts as well. An interesting department will be the International Dairy shed, where butter and cheese will be made by machinery. The whole of the buildings and the drainage of the site—an operation that has taxed the resources and patience of the officials during the late wet season—have been carried out under the personal superintendence of Messrs. Thomas Penny and Son, of Taunton, the superintendents of works to the society. The land drainage, we hear, has cost £2,500, and looking at the work that has been performed, and the formation of roads, considerable credit is due to those intrusted with the undertaking. We understand the whole of the erections will be sold by public competition after the close of the Exhibition.

THE ARCHEOLOGY OF ADEL CHURCH.*

WE have received a copy of a work upon the archaeology of this very remarkable Norman church, of the West Riding of Yorkshire, a building little known probably to some of our readers, but one of extreme value to the antiquarian, and particularly rich in the symbolic art and the grotesques of the period. The author, the Rev. Henry Trail Simpson, M.A., late rector of Adel, appears to have devoted a considerable portion of his life to the delineation of the topography and historical associations of this parish; and in the "Letter Dedicatory" to the members of the Royal Archaeological Society, who visited the parish in 1866, he states the idea of publishing the work was suggested to him by that visit. At that examination a curious stone, remarkably incised, was discovered jutting out from the north-west corner of the foundation, which led to the discovery of many others of a similar kind, which are deposited in the vestry, and which are described and engraved in Mr. Simpson's book. Adel is made the subject of a learned dissertation in the opening chapter, in which its

* *Archeologia Adelenensis; or a History of the Parish of Adel.* By HENRY TRAIL SIMPSON, M.A. London: W. H. Allen & Co., Waterloo-place.

name and topography are discussed. The etymology of the word "Adel" has undergone various changes. "Addle" and "Adhill" have been used in previous times, and the term is probably a corruption. The author supposes that a Phœnician colony might have existed at Adel, and the worship of their goddess Aidan been established—hence the name Adhill or Adan-hill, and that the word Adel signifies great or powerful god. But we pass on to speak of the remarkable relics that are deposited in the vestry. These consist of incised stones, "querns," round, flat, or conical stones for grinding corn, "Saxon wheel-crosses" as they have been called, and an ancient stoup or mortar with sculptured figures on three sides, on one of which is a heart and on another a human figure with serpents on each side—to all appearance a mythological symbol. A similar figure occurs at Ilkley, which is engraved also. Three Roman altars, moulded and sculptured, and the "capital of a Roman column"—though we cannot, from the engraving, believe it to be one—are among the other relics. Stone coffins, of plain Norman character, are to be seen in the churchyard, one with a lid. The author shows that there was a Roman station at Adel: this is proved by the remains found in the common and neighbourhood; the church is supposed to have been constructed of materials used before for building, and it is conjectured that some Roman building at Blackhill was broken up and used for the church. A more probable idea is, that the Saxon church mentioned by Whitaker at Blackhill supplied the materials, and the Saxon wheel-crosses we have mentioned seem to indicate this origin. Numerous allusions are quoted bearing upon the antiquities at Adel, the gist of which goes to throw light upon the relics, while the Adel altar, inscribed to the goddess of the Brigantes, proves the antiquity of the parish. Remains of pottery, encampments, and altars have been found at Blackhill, Adel Mill, Rombalds Moor, Wakefield, and Ilkley. As regards the church, it is claimed that the building is an entire specimen of Norman, unalloyed with admixtures of later date. In Part II. the author traces the vestiges of ancient religions, and tries to establish the fact that the district of Elmete was formerly a religious district of remarkable character. We cannot follow Mr. Simpson in his references to primeval creeds as illustrated at Adel, though we fully agree with him that heathen and revealed types of religious worship often correspond with each other. It is asserted that the huge temples and circles of Avebury or Stonehenge represented the sinuosity of the form of the serpent, but we are not justified in accepting this idea as an established fact. We leave this portion of the work to the archaeologist interested in symbolic representation, and refer to the singular stones and carved work at Adel. The author thinks the stones discovered at Adel, already mentioned, with their rude sculpture, take us back to a period earlier than the 9th or 10th century, for "if the present church of Adel was built in 1135 A.D., there must have been a church at Adel prior to this rebuilding, probably a Saxon church erected under the auspices of Paulinus." He does not think they are Christian, and he cannot see, as some have done, that they have the rudiments of a cross upon them. "In fact," he observes, "I imagine them to be Saxon monuments of a heathenish character, and not Christian." There is certainly, from the engraved representations of these stones given, a strong presumption for thinking them to be heathen in conception and execution. They all bear, besides Runic characters, the phallic circle and central cross, with other symbolic incisions of the sun and moon. The engravings given of them represent them as about 3ft., or 2ft. 9in. by 1ft. 4in. and 1ft. 9in., and of

irregular shape, rounded at the top. Some of the devices show concentric circles, others have intersecting arcs, a series of semi-circles with a boss representing the sun, rays, &c. Mr. Simpson mentions similar stones that have been found at Thurnby, Leicestershire, Rombalds Moor, &c. The former are illustrated, and show a series of straight lines of cross-like character. Of the exterior of the church several sculptures of a typical character are illustrated. The cuts given of Adel Church in its present and restored conditions are not good of their kind; but we are led to follow the explanations offered of the plan, the large churchyard, and sculpture. The large and bleak churchyard is thought to be emblematic of the world, barren and waste, the church the ark, while to the windows are attributed a symbolic meaning. One singular grotesque is a head of a monster on the apex of the gable of the beautiful south Norman porch; the author observes that it is intended as the image of Satan, and its position here was to thwart man on his first attempt to escape from the effects of sin. Below the apex in the tympanum are rude sculptures of the cross, the *Agnus Dei*, and, just above the arch crown, the Saviour on His throne. In the side spandrels are representations of SS. Mark, Matthew, John, and Luke, while the sun and moon occupy triangular spaces between these and the centre subjects. The symbolism is carried out in the capitals of the outer arches, but we hesitate to think the zigzag or dental enrichment round the arch is emblematic of the brilliancy of the rainbow that encircles the throne. Leading up to the enthronement, over arch, are two stems, on the east side, a single stem dividing into four branches, each having a serpent's head; and on the west side two stems dividing into four, ending in some flower. The former is thought to illustrate the Fall of Man, and the four rivers the acknowledged symbol of the four Gospels, the others illustrative of the Law and the Prophets. The corbel line of heads along the eaves is interesting, but the drawing scarcely does justice to so unique an example. The heads are chiefly grotesque, the stones of arcade being simply moulded with a double round in each half of the corbel. The channel arch is a splendid specimen of three orders, the outer order enriched with the dog-tooth and a row of grotesque heads, each with the mouth open ejecting monstrous products; the next is a cable line, and the lower the zigzag. We have no further space to describe the capitals and their symbolic significance, but only to remark that the whole of the sculpture, both without and within, is intended to convey the Christian's perpetual conflict with the world and evil spirit. The Norman font and windows are also described and illustrated, and the book will be read with interest by admirers of Early Norman art. The frontispiece does scant justice to the church, and we may refer the reader to a better illustration of it that appeared in the *BUILDING NEWS*, Vol. XXVIII., for April 30th, 1875, wherein plan and details of the font also will be found.

THE RECENT EXCAVATIONS OF THE ROMAN FORUM.*

(Continued from p. 673.)

THE whole of the south-western side of that part of the Forum called by some authors the mid-Forum, is bounded by one of the sides of the Basilica Julia, occupying a rectangular space of about 400 by 160 ft.; the inclosure was formed by an arcade of which there are considerable remains at the west corner, where owing to the rapid rise of the ground next the *Vicus Juguarinus*, this corner of the building was constructed against the sides of the hill, and having become

buried by the falling of the hill-side, has been better preserved to us than the other portions. Abundant evidence, however, has been found amongst the fragments of the building to enable a restoration to be made of part of the inclosing colonnade, which has been done by Signor Rossa, who has also caused brick piers to be built indicating the position of the piers of the entire building. Antiquarians seemed to be quite agreed that this edifice was begun by Julius Caesar and finished by Augustus, who afterwards rebuilt the original edifice on a more extensive scale after the destruction by fire of the first building. The honour of this restoration was attributed by the Emperor to his grandsons and adopted sons Lucius and Caius, and the Basilica for a time was known by their names; it was repaired in the second century and underwent some restoration in the reign of Dioclesian, but the architectural features of the building of Augustus appear to have been preserved. This Basilica was the court of the *Centum Viri*, which had in the time of the younger Pliny, who practised before it, not less than 180 judges, and it is mentioned by Dio as one of the places in which the Emperor Trajan sat to administer judgment; it was surrounded on three sides by streets, the *Vicus Juguarinus* already referred to on the north-west; on the northern side was the principal street, part of the *Via Sacra*, which traversed the Forum in the direction of its length; and on the south-eastern side it is bounded by a street identified as the *Vicus Tuscorum*, which is known to have led from the Forum to the Velabrum and where now stand the church of St. Giorgio in Velabro, lately become more known to us as being connected with our English Cardinal Newman, and the *Circus Maximus*: this street vies with the *Via Sacra* in its frequent mention by ancient writers and in its religious character: being the route taken by the great processions on the occasion of the *Ludi Romani*, in which the statues of the gods were carried on cars from the Capitol through the Forum to the *Circus Maximus* at the back of the Palatine Hill. The *Vicus Tuscorum* had also the character of a busy and fashionable tradesmen's quarter, and was considered as the Bond Street of Rome, in later times it was called *Vicus Juguarinus*, apparently from the spice shops which were situated there; in the time of Plautus the neighbourhood of this street and the district behind the Temple of Castor had a bad reputation as the haunt of rogues and infamous persons. The remains of a ruined pedestal about 10 ft. by 8 ft. has been uncovered at the north-east corner of the Basilica of the statue of Vertumnus. The whole of the Basilica Julia is covered with paving, that of the arcades being of, I believe, Travertine stone, and the centre portion with yellow and black marble, all perfectly level but much crushed and fractured; the paving of the arcades has been properly repaired. On the pavement of the arcades, especially on the north-east next the Forum, there are many inscriptions and also a number of rudely incised figures, most of them being circles variously divided, one I noticed being rectangular in form; these are supposed to have been made by boys for playing games; there are also rude imitations of other objects, one intended to represent an owl, one a branch of a tree and other subjects: Opposite to the Basilica on the N.E. side of the *Via Sacra* formerly stood the Tabernæ or shops of the Forum, originally founded by King Tarquinius Priscus; they were naturally then required for the trades generally carried on in a market-place, hence the butchers' stalls, from one of which Virginius took the knife to stab his daughter. The schools for children were also among the shops in the forum, and it is said to be there that Appius Claudius first saw Virginia reading. In ancient times there appear to have been two rows of these shops at first used for general market purposes, but afterwards more particularly as jewellers' shops; no doubt very shallow, like the shops on one of the bridges at Florence or on the Rialto at Venice, or like the Pantiles at Tunbridge Wells. They were standing in the times of Cicero and Livy, but they were burnt down shortly after the death of Agrippa, B.C. 12; and we may doubt whether what was then destroyed was ever rebuilt, as we now find seven low brick piers about 13 ft. square, supposed to be the remains of pedestals on which statues or columns were placed. Some fragments of statues have been found amongst the excavated ruins, which it is asserted are part of statues

formerly placed on these pedestals; if so, they must have been quite small and probably numerous. In the open spaces of the mid-Forum, near its most western side, is the monument of Phocas, consisting of a Corinthian column which long stood with its base buried in the Campo Vaccino; it was supposed until 1813, when its base was excavated, to be the remains of a temple. It was then found to stand on an isolated pedestal mounted on a broad square base of tufa masonry and brickwork; and the pedestal bore an inscription which shows it to have been erected A.D. 605 by the Exarch Smaragdus, in honour of the Emperor Phocas, probably the last of the triumphal buildings erected on the Forum. Near the eastern corner of the base of the column of Phocas is one of the most interesting monuments which have been discovered during the recent excavations in the Forum. It consists of two marble slabs, about placed parallel to each other, a short distance apart. Antiquarians call them *Plutei*, and suppose that their use was to form a gangway through which who coming to vote could as they passed in single file deposit their voting ticket. They were discovered in 1873. The outside of each slab is carved with bas-reliefs of a very fine character, and not greatly injured on the inside. Each bas-relief is represented the same subject, namely, a bull, a sheep, and a pig, prepared for the *Secovotantia Sacrificia*. The sculpture on the external faces represents two scenes, which are differently described by antiquarians—one attributing them to scenes in the life of Domitian, another to scenes in the life of Titus (and this seems to be the most accepted explanation), and another to scenes in the life of Septimius Severus. However, these we may leave for antiquarians to discuss and settle, and proceed to describe what has the more special interest for us, namely, the backgrounds of the sculpture scenes represented on the outer faces of the *Plutei*; and this I propose to do in the words of the author already referred to, Mr. A. Nicholls. When we turn to the backgrounds of the two bas-reliefs we find that they both represent the scene that was in reality before the spectator (the Forum Romanum), and in this lies the important topographical interest of the sculptures.

The locality of (what our author supposes to be) the Burning of the Registers is most easily recognised, and may be conveniently taken first. In the foreground to the left of the spectator is a fig-tree, and next it a statue on a pedestal. In the background behind the figures were five arches of a building divided by piers with half-columns, or pilasters of the Tuscan order. At a short distance from the end of this building is a hexastyle Ionic portico with a pediment. Then after a short interval, through which an arch is seen in the further distance, is another hexastyle portico and pediment with Corinthian columns. A part of the bas-relief to the right is lost, but in the foreground is a portion of the rostra upon which the Emperor was seated. In order to identify the scene, it is only necessary for the spectator to turn from the sculpture to the ruined buildings before him. In the Corinthian columns of the Temple of Vespasian he will recognise the remains of the Corinthian portico, in the portico of Saturn the Ionic portico of the bas-relief. The arch seen in the distance between the two porticoes would probably be a part of the loggia of the tabularium. The long line of arches with piers between them will be found in the Basilica Julia, with its ornaments of Tuscan architecture. The whole of the background may thus be explained by the aid of the ruins which remain. Of the objects represented in the foreground no distinct traces are now to be seen. They consist, as has been mentioned, of the rostra to the right and a fig-tree and statue to the left. On the other bas-relief, which is more perfect than the first, the same statue and fig-tree are seen in the foreground; on the right and next to them behind the figures are seven arches with intermediate piers similar to those of the first sculpture. Then after an interval of some width is a Corinthian portico, which is represented as having five columns, and finally to the left an arch which appears nearer to the spectator than the portico. In the foreground are the rostra, from which the Emperor is speaking. It will be observed that in the foreground of each sculpture we have the rostra on one side and the statue and fig-tree on the other, but in one representation the rostra are on the right, in the other on the left. In the two scenes the spectator is supposed to be placed on different sides

* A paper by EDWARD TANSON, F.G.S., F.R.I.B.A., read before the Royal Institute of British Architects, June 9, 1879.

of the rostra, but in both cases the statue and fig-tree are seen in the same relative position or nearly so, the tree to the left of the statue. In order that these two objects should be so seen from the right and left of the rostra we must suppose both of them to have been before the rostra at about equal distances from it. Thus, though the spectator has changed his position from one side of the rostra to the other, his situation with reference to the statue and fig-tree remains nearly as before, and as the one sculpture ends with those objects on the left, and the other begins with them on the right, the background of the buildings behind these two objects in the second sculpture may be expected to begin at about the same point where it terminated in the first. With this clue we find in the piers and arches of the second bas-relief a continuation of the long colonnade of the Basilica Julia. In the wide interval to the left of the basilica the portico of the Temple of Castor might be expected to be seen, but the artist has not thought fit to introduce this monument, possibly because hidden from the rostra by some nearer objects. In the portico with the Corinthian columns we may recognise the Temple of Divus Julius, the podium of which has been recently excavated, and which is represented in medals of Augustus and Hadrian with a tetrastyle Corinthian portico. The five columns may be assumed to be a mistake, as this form of portico is unknown. The arch behind the rostra was probably that of Augustus, of which we have some obscure mention as standing near the Temple of Julius. The explanation here given of the first background (in which the Temples of Vespasian and Saturn appear) agrees with that of Signor Brizio. In the other background that learned antiquary thought we might find the Basilica Emilia and some other buildings of the north-eastern side of the Forum. This opinion was founded on the supposition that the two views were taken in opposite directions, a supposition which is contradicted by the similar relative position of the statue and fig-tree in both scenes. The two sculptures are in fact united by the recurrence of these objects, and present us with a partial panorama comprehending the south-east, south-west, and part of the north-west side of the Forum as seen from the neighbourhood of the rostra. We may now turn to the identification of the objects in the foreground. Among these are the rostra of the Forum. The removal of this monument from its site at the edge of the Comitium, where it stood till the time of Cicero, is testified by Dion and Asconius, but its subsequent position has not been ascertained, except so far as the sculpture before us enables us to do so. The statue seen in both the bas-reliefs represents a figure nearly nude, but shod with a sort of loose boots. On his left shoulder he bears a full wine-skin, and his right arm (which is lost in both sculptures) appears to have been raised in the air. This figure has been recognised as that of Marsyas, who is represented with the attributes of a satyr or Silenus, a character ascribed to him by Herodotus and Pausanias. To those who desire to carry further the inferences which the author so largely quoted has arrived at, I refer to the second chapter of his book, in which he concludes that these bas-relief enable us to determine with accuracy the position of the equestrian statue of Domitian, the Lucus Curtius, the statue of Marsyas, and the rostra; but excepting the ruined base of the equestrian statue no trace of either of the other monuments remains. On the north-eastern side of the Forum may be seen some traces of the ancient Via Sacra. The south-eastern end of the mid-Forum is bounded by a cross road extending from the N.W. corner of the Temple of Pollux in a north-eastern direction until it joins the Via Sacra. Before leaving the mid-Forum, I should refer to the Cloaca Maxima, which is in part uncovered, and can well be traced passing under the Basilica Julia, and obliquely nearly in a northerly direction until it is lost under the still unexcavated bank on the N.E. side of the Forum. The surface of the Forum, as we now find it, is paved where it was intended for the use of carriages with large polygonal blocks of hard grey volcanic stone, called by the ancients *silex*, although its composition in fact does in no way correspond with the meaning of this term as used in science, and where it is intended for foot-passengers only, with rectangular slabs of Travertine stone. The ruts caused by the chariot wheels, as at Pompeii, are very noticeable, especially at the sharp turn of the road at the corner of the Temple of Castor, and from some cause which I find it difficult to

explain, the stones, and it is the same at Pompeii, are worn away at the joints, so that each stone presents a convex surface; at one part of the roadway near the bottom of the Clivus Capitolinus, is a more perfect portion of the roadway where the joints are well squared, apparently more recent and less worn, and where the rounding of the edges is not perceptible. Adjoining the Vicus Tuscus at the south-eastern end of the Forum are three Corinthian columns which formed one of the landmarks of Campo Vaccino, formerly known by the name of Jupiter Stator. Canina at one time considered them as part of the Curia Julia, but they are now recognised as the Temple of Castor and Pollux, the divine twins, whose supernatural interpositions are so curiously interwoven with the traditions of the early struggles of Rome. The Temple of Castor—originally built 482 B.C.—was rebuilt by L. Melittus Dalmaticus B.C. 119, and whatever may have been the character of the original temples, the edifice of Melittus was one of considerable size and importance, and was frequently used for the meetings of the Senate. This temple was amongst the numerous public edifices which were rebuilt in the time of Augustus; it was erected by Tiberius, in his own name, and that of his brother Drusus, out of the spoils of the German campaign, and although dedicated to two divinities it generally bore the name of Castor only. About 20 feet from the eastern corner of the steps of Castor are the remains of a low round construction, apparently a basin of water, which is probably the Lake of Jemena, and the pool or spring referred to in early story at which Castor and Pollux gave water to their heated steeds after the battle of the Lake Regillus. A little further east is the round podium of a circular building, which is supposed to be the remains of the Temple of Vesta, but authorities, as usual, differ on this point. The age of the temple which existed in the time of Augustus, and which was then covered by a bronze dome, is unknown—it was burnt down in the great fire of Nero, and was probably built by Vespasian, but again burnt down during the reign of Commodus. The temple must, judging from the size of the ruins of the base, have been quite small, and the fact of its having been, in the time of Augustus, covered by a bronze dome seems to strengthen this conclusion. On the southern side of the temple are some ruins half hid in the still unexcavated bank, which probably occupy the site of the houses of the Vestal Virgins. North-east of the Temple of Castor and Pollux are the ruins of a podium of a temple, which it is believed faced N.W. toward the Capitol, and is supposed to have been built on the spot where Cæsar's body was burnt. On the site of the cremation the partisans of the Dictator, very soon after the event, placed a column, described as Numidian marble nearly 20ft. high, and inscribing "Parenti Patrie"—and before the column was an altar; the column and altar were afterwards removed by Dolabella, and the Temple to the deified Julius Cæsar was erected soon after by Augustus. On the N.W. side of the temple there are very distinct traces of a wall, segmental on plan, with the segment portion built into the podium of the temple which now covers and conceals it. Traces of the plinth and marble lining of the straight portion of the construction abutting N.W. on the Forum still remain; this is said to have been the Rostra Julia. From this rostra Julius Cæsar is said to have harangued the people, as well as from the platform of the adjoining Temple of Castor and Pollux; and here too it is said that Mark Antony addressed the people; and close by where the temple now stands the pyre was hastily constructed on which the body of Cæsar was burned. Here also Tiberius read his funeral speech on the death of Augustus.

I have endeavoured to note the position and present condition of these ruins which cover and surround the Forum, giving only so much description as seems necessary to identify them. Nothing is more striking, considering how large a portion Roman history fills in the history of the civilised world, than the small area within which the scenes of Roman history were enacted. The Forum of Rome was the focus of all, and the Forum of Rome is not actually larger than Lincoln's-in-fields. And the Via Sacra through which we are told the Emperors of Rome passed—followed by captive potentates—with the trophies of victory and long trains of armed warriors and slaves, and on their way to the Capitol, where the victorious Emperors proceeded

to solemnise their triumphs with religious rites—and the captive Kings were led to their prisons—and where the great annual religious processions of the people, carrying their images and their gods, passed on their way to the Palatine Hill—this great thoroughfare of Imperial Rome was only 12ft. wide.

DISCOVERIES AT ST. PAUL'S CATHEDRAL.

A PAPER describing the remains of Old St. Paul's Cathedral recently found has been read by Mr. F. C. Penrose, M.A., surveyor of St. Paul's Cathedral, before the Society of Antiquaries. The first portion of the lecture recapitulated what had been done in the south-west churchyard, and which the author laid before the Royal Institute of British Architects, January last, as noticed by us at the time.* The more recently discovered objects were then detailed. Mr. Penrose stated that firstly, the extreme north-west angle of the north transept had been found, which terminated with a flat pilaster in Portland stone, answering to one of that character at the south-west corner of the south transept, and which were obviously part of Inigo Jones's incrustations, as shown by Hollar. The next point was the search for Paul's Cross, and the remains of the east end of the old Cathedral, whilst the works for the conversion of the burial ground into a cemetery garden, by the joint arrangement of the Dean and Chapter and the Corporation of the City, were going on, and which offered an opportunity which was not to be lost. In the search for Paul's Cross the surveyor was aided chiefly by two documents; one a perspective view, preserved in the Pepsian collection at Magdalen College, Cambridge, which showed it from the east, and the other a plan which, although very inaccurate on some points, gave true representations of what had been found on others (the "Oxford plan, No. 2," as referred to in the paper read before the Institute). This latter being the only plan upon which the cross was shown was the principal guide. All other representations besides the two above mentioned appeared of less value.

The search was successful, although as it turned out, it was rendered precarious by the misleading directions of the plan named the "Oxford plan, No. 1," in the paper already referred to, which showed the lines of the old cathedral at the east end about 30ft. further north than they were at last found to be. "Paul's Cross" consisted of an octagonal wooden erection, probably about 17ft. from side to side, forming a pulpit, raised upon an octagonal platform 37ft. from side to side, or 40ft. from angle to angle. The lower courses of about half of the wall supporting this outer octagon was found, with the springing of a pointed brick arch, which carried the pavement of the platform, and a small part of the substruction of the central pulpit. The other half had been destroyed in preparing the foundations of the present cathedral, and the remains at the north-east corner were peculiarly deep. The site as discovered was much nearer the cathedral than general opinion had placed it. For instance, in the Ordnance Survey map, in forming which very great pains had been taken in investigating the documentary evidence available, the site is shown 70 or 80ft. distant. The foundations discovered were no doubt those of the restored cross, built by Bishop Kemp, about 1470 A.D., and which had played an important part during the time of the Reformation. The sermons there preached had in fact performed the duty now undertaken by the public press, of informing people's minds, by the authority of those who for the time being were in the ascendant, of the various phases of that conflict. Latimer and Ridley on the one side, and Fisher and no doubt Bonner on the other side, besides others, preached for and against the Reformation. The last occasion on which it is heard of, is that the Puritans of the Commonwealth ordered it to be levelled with the ground in 1642.

After the discovery of Paul's Cross, search was made for such remains of the east walls or buttresses of the old cathedral as might possibly be remaining under the churchyard wall, and part of a buttress was soon found, but owing to the misleading indications of the plan already re-

* See BUILDING NEWS, for Jan. 31st (p. 132), and Feb. 14th (p. 183); also article on "Improvements at St. Paul's," in issue for May 9th (p. 501) ante.

ferred to, in reliance upon which in the paper read before the Architects' Institute, it was argued that the axis of the old choir must have been deflected from that of the nave, it was difficult to assign to which part of the east end this buttress and some other parts of this wall foundations really belonged. At last, however, a portion of a buttress close under the present apse, where any remains were hardly to be hoped for, was discovered, and cleared up the question: proving that there was no deflection, but that the plan which had so distinctly represented the coincidence of the centres of the old and new cathedrals at the east end was in error by about 30ft.: the axis of the old cathedral being about that dimension to the south of the present. The plan referred to seemed entitled to more confidence, as it was found to be extremely accurate in all that respects the present cathedral and the form of the churchyard, but proved very inaccurate as respects Old St. Paul's. Search was now made for the inside of the south wall of the old cathedral, and was rewarded by the discovery of some fine shafts and bases of the chapel which was built as a crypt under the choir, when the cathedral was lengthened about the year 1260, and was called Jesus Chapel, and which subsequently became St. Faith's Church under St. Paul's, and also part of the pavement. The floor of this chapel is about 13ft. below the present ground, and must have been about 4ft. or 5ft. below the original read which passed between the cathedral and St. Paul's school. A discovery has also been made of the extension of the cathedral westward by means of an excavation which the Dean and Chapter have allowed to be made near Queen Anne's statue, and which shows the extreme length of the old cathedral (omitting the western portico added by Inigo Jones) to have been about 585ft. The extreme breadth at the transepts was 302ft. The axis of the present cathedral is to the north-east; that of the old was to the south-east. The point upon which they turn is exactly at, or very near, the centre of the dome. The angle between the axes is about 7°.

NOTES IN THE WEST.

TO-MORROW the foundation-stone of the new Eddystone Lighthouse, off Plymouth, will be laid by the Duke of Edinburgh, who holds the post of Elder Brother of the Corporation of the Trinity House. The cost of the new lighthouse will be £70,000. It is proposed to light the new beacon by electricity. It is now just 120 years since Smeaton's grand lighthouse was finished. This structure still stands boldly towering aloft; and it is the rock beneath, not the engineer's work, which has become unsafe. The ocean currents have changed their courses somewhat since Smeaton erected his beacon. Portions of the bases of old edifices, once dry and high out of water, are now covered, whilst other murens formerly, are now above water places covered by seaweeds. The pressure upon the building by the waves is computed to be three tons to the square foot.

The *Daily Telegraph* made a curious and characteristic blunder in a leader upon the Eddystone on Friday last. The writer laid stress upon the vast obligations which, all who, like himself, were familiar with the navigation of the English Channel, must have felt themselves under, for the lights that guide the mariner at every point, and then went on to inform his readers that the present Eddystone Lighthouse is built upon "the Bishop's Rock, and guards the shoals and breakers of the Scilly Islands"! And, as if to make this topographical discovery the more wonderful, the article refers to this Eddystone Lighthouse on the Bishop's Rock as "hurling back the waves in sight of Plymouth Hoe"! Considering that the Bishops' Rock and the Plymouth Hoe are more than 120 miles apart, this stretch of vision is remarkable.

A new church will probably be shortly built at Penzance, and another at East-the-Water, Bideford. In each instance it is most likely local architects will receive the commission.

Perhaps the most picturesque building in the whole of Great Britain is the seat of Sir J. St. Aubyn, Bart., M.P., upon St. Michael's Mount, situated in Mount's Bay, some quarter of a mile from the shore, where the pretty little village of Marazion stands:

"Majestic Michael rises; he whose brow
Is crowned with castles; and whose rocky sides
Are clad with dusky ivy!"

The restoration of the noble pile, situated upon the summit of the rock, has been in hand some six or seven years, from the designs and under the superintendence of the noble owner's near relative, Mr. James Piers St. Aubyn, architect, of Lamb Building, Temple, E.C. A perspective view of this building appeared in these pages some years since. The rock, which is composed of granite and slate, towers some three hundred feet above the level of the sea, and upon its rugged summit stands the mansion and church. The works have been carried out without the assistance of a contractor, under the trusty supervision of a clerk-of-works, and the additions are wholly in grey granite work. It is but due to add that the building exhibits some of the finest work in that material it has ever been man's privilege to see. The works are now drawing to a close, and it is expected that Sir John and his family will return to their romantic and beautiful home next month.

Another large building upon the same coast, now nearing completion, is Rousdon. But, whilst St. Michael's Mount is on the extreme western coast of Cornwall, Rousdon is on the eastern edge of the neighbouring county of Devon, just one hundred and thirty miles away as the seagull flies. But, while at St. Michael's the surroundings boast of all that Nature, in her brightest moments, can bestow, Rousdon has no such advantages, and is an artistic pile reared where tree almost refuses to grow, and where sea-fogs hide, for a greater part of the year, all that the skill of man has erected. Commenced in 1871, a series of illustrations in these pages (June 26, 1874, and again in May 12, 1876) gave a good idea of the work in progress. The architects for this important undertaking are Messrs. Ernest George and Peto, of 11, Argyll-street, London, W., and the mansion and its surroundings are being built, at a vast cost, for Sir Henry W. Peek, M.P. for Mid-Surrey. The group embraces the immense mansion itself, the church of St. Pancras, spacious schools, large stables and other outbuildings, three lodges, and a water-tower, the whole being erected in that artistic style of domestic architecture which is so essentially Mr. Ernest George's own. Mr. William Prosser, for very many years with the late Sir Gilbert G. Scott, is the very courteous and energetic clerk-of-works in charge of the job. It is hoped that the whole may be finished by the end of next year.

At Tresco, the second in size, and perhaps most picturesque, of all that community of one hundred and forty odd islands going to form the isolated Atlantic group known as the Scilly Isles, a new church has been built, at the cost of Mr. Dorrien Smith, the Lord of the Isles. It is just completed, and was consecrated by Dr. Benson, the Bishop of Truro, on Tuesday. Only six of the Scilly Isles are inhabited, and Tresco, upon which Mr. Smith himself lives, has a population of 266 souls, all told.

Stoke Gabriel Church, near Totnes, has been under restoration for some time under Messrs. Hayward and Son, of Exeter, and the work therein is nearly complete.

Pinhoe Church is being restored from the designs of Mr. R. Medley Fulford, of Exeter, and for Monkokehampton Church a handsome reredos is being made from designs by the same architect. This reredos is the gift of Sir Stafford H. Northcote, Bart., the Chancellor of the Exchequer, to whom the manor belongs. It is at present being carried out by Mr. Harry Hems, of Exeter. Mr. Edward Ashworth, also of Exeter, has the restoration of Shobrooke Church in hand, and additions to Silvertown Church are being made from the designs of the same gentleman.

Iddesleigh Church is being thoroughly restored, from the designs of Mr. Charles S. Adye, architect, of Bradford-on-Avon; and Petrockstow Church, having been for some time under restoration, under the superintendence of Mr. John F. Gould, of Barnstaple, is drawing near completion.

These last-named eight churches are all within a radius of twenty-five miles of Exeter.

In the ancient city itself, Mr. Butterfield's new schools at Mount Radford are beginning to get above ground. Messrs. Stephens and Bastow, of Bristol, are the builders, Mr. Newcombe the clerk of works, and Mr. Hampton the foreman. The huge new railway hotel, just opposite the South Western Company's station, is complete and open. It is a great building, designed by Mr. C. Ware, a surveyor, of Exeter.

Unfortunately, by a curious oversight, it has been built upon an angle some yards out of the square with the rest of the street wherein it stands (Queen-street, a long, straight, and noble thoroughfare), and the ill effect produced by this blunder may be better imagined than described.

In a recent number (March 28, 1879) Mr. Harry Hems described some very interesting old houses in Exeter, built upon the ancient bridge over the Exe. A dreadful case of child-murder and mutilation in that city has just occurred, thrilling the country with horror. The remains of the unfortunate child in question were first discovered in the water beneath these very houses.

It is being proposed that a new church be built at Newport, a suburb of Barnstaple. Messrs. Gould and Son, the well-known church architects, of the latter town, were commissioned to prepare plans for the same, and very satisfactory these drawings proved to be. Mr. Abbott, however, formerly partner in the firm of Messrs. Flockton and Abbott (now Flockton and Gibbs), architects, of St. James-row, Sheffield, has recently come to reside at Barnstaple, and has just given plans for the proposed church gratuitously, and a gift of fifty pounds into the bargain! It is said there is no comparison between the merits of the two designs, but, under the circumstances, art and filthy lucre are at rivalry, the one with the other, and the building committee are at a loss upon whom to bestow the apple.

Some curious houses, supposed locally to be of the Queen Anne type, are being erected near to where this proposed church will stand. They are built of red bricks, or tiles, in courses of 3in. by 6in. deep respectively, and at the angles of the bay windows, &c., these tiles are mitred! Mr. Alexander Lander, of Barnstaple, is the architect for these buildings. The tiles and bricks used in the fronts are also supplied by him, Mr. Lander being the principal of extensive potteries, as well as carrying on the business of a manure merchant.

ARCHITECTURAL ASSOCIATION.

WE give this week, in continuation from last issue, p. 658, the second portion of Mr. H. W. Pratt's paper, together with the subsequent proceedings, at the closing meeting of this Association held a fortnight since.

And now let us briefly glance at the arrangement of the French churches. With a few notable exceptions, we shall find them following one main type—viz., the Latin cross, and an apsidal choir. This comparatively simple plan has its varieties—e.g., the choir aisles are frequently double, and sometimes the nave aisles; and not only do radiating chapels form a feature of the choir alone, but continuous lateral chapels often line the nave. Hence we have a grandly-developed plan, as at Notre Dame, Paris, and the cathedrals of Bourges, Coutances, Rouen, and Tours; or without nave chapels, as at Amiens and Chartres Cathedrals, and St. Sernin, Toulouse, the last-named being further developed by the addition of an aisle round three sides of each transept. At St. Nazaire, Carcassonne, we have a line of eastern chapels, such as one sees in certain churches at Verona, Venice, and Florence. There are three on either side of the choir, and these were added to the transepts in the 14th century; they are separated from each other by open-tracery divisions, and produce an unusually beautiful east end. At Bourges and Mantua Cathedrals, and a few other churches, there are no transepts, while Angers and Vannes Cathedrals, and some other examples, have no aisles. Dol Cathedral is noteworthy as possessing a square east end, while the Cathedrals of Lyons and Vienne have an east apse, but the aisles terminate square. Another feature of considerable importance and much effect is the adoption of a lantern at the crossing. This feature is circular at the Abbaye aux Hommes, Caen; and at Lisieux it is square; but in others it is octagonal. Of the churches which depart from this general French type first and foremost is that of St. Front, Perigueux, said to be a copy of St. Mark's, Venice, and built by the same architect, the plan being that of the Greek cross surmounted by five cupolas. At the west end are the remains of an earlier church, over which stands a lofty and picturesque tower. The principal entrance is by the north transept, which is preceded by an open arcaded narthex. Each transept has a small apsidal chapel. The east arm of cross used to terminate in a 14th century apse, but there is now a new apse in the

style of the original church, but much more elaborate and not very satisfactory. The lecturer expressed great regret at the wholesale restoration which is now being carried out here, by which an ancient and most beautiful church has been transformed into a brand-new edifice. Perigueux has another domical church, formerly the Cathedral, and now called l'Eglise de la Cité. Only two compartments remain, and these are of considerable span, about 50ft., each surmounted by a cupola. As in St. Front, the supporting arches are pointed to a minute but discernible extent, and herein lies a distinction between these and St. Mark's, the arches of the latter being round. Probably when this church was complete it was similar to Cahors Cathedral, which has two demical compartments of about the same span and an apsidal choir with three apsidal chapels, the supporting arches again being pointed. Le Puy Cathedral has a nave divided into six compartments, each surmounted by an octagonal cupola. There are aisles and transepts, the latter divided in a peculiar fashion into two parts by a pair of columns supporting a groined soffited gallery. The choir has now a square end, but this has been rebuilt for increase of accommodation. At the crossing is a domed octagonal lantern rising out of a circular cupola. Owing to the steep slope on which the church is built, the entrance has been contrived rather ingeniously. It is approached by a steep street, ending in a long flight of steps, at the top of which are three lofty arches. Passing through these, you still ascend steps along a stepped vaulted corridor under the nave. At the end of this corridor is a wide doorway, which opens upon a flight of steps left and right, the former leading to the cloister and the latter to the church, which is eventually entered in the south aisle. It is supposed, however, that the original intention was to pass under the whole length of the nave and enter the church in front of the altar; it is quite possible that such an entrance once existed, and that the present is a subsequent alteration. Fontevault Abbey Church is not unlike Angoulême; it has a choir aisle and three instead of four chapels to apse, but, sad to say, the abbey buildings now form an extensive prison! The nave of the church has had upper floors inserted to make dormitories for the prisoners, the ground floor being their refectory, while the transepts and choir remain for the chapel, and in a corner of the south transept are placed the recumbent figures of Henry II. of England and his queen, Richard I., and the widow of King John, but their bones have long since been seized and scattered. St. Ours, at Loches, is certainly a unique church. It is of 12th century date, and consists of a nave in two compartments, each of which is covered with a lofty octagonal conical cupola open up to the top, and perfectly plain. At the crossing is a tower, which forms an octagonal cupola with a circular light at the apex; there are transepts with apsidal chapels, and a small apsidal choir. At the west end is another tower, and west of this a large square narthex, with fine Romanesque doorways. The exterior is rendered singular by the two lofty pyramids between the east and west towers, though, taken in conjunction with the buildings surrounding the castle heights it is picturesque and striking. Neither in France nor Italy do we see the beautiful cloisters with which we are so familiar in this country, but there are several interesting examples. They uniformly possess arcades of small arches mostly springing from double shafts, and though we miss the tracery we have instead finely sculptured capitals. On the north side of the Abbey Church of St. Pierre, Moissac, near Toulouse, is a beautiful 12th century cloister, one of the piers bearing the date 1110. The arches are moulded and pointed and spring alternately from single and double shafts; at each angle and in the centre is a square sculptured pier. All the capitals are beautifully sculptured with Scriptural subjects, and have explanatory inscriptions attached. This is one of the most remarkable cloisters on the Continent, and, wonderful to say, is in excellent condition, and without sign of restoration. He understood that a young English architect had made elaborate drawings of this abbey, but could not ascertain his name. The author also described in detail the cloisters at Le Puy Cathedral, San Zenone, Verona, Montmajor Abbey, Mont S. Michel, San Matteo, Genoa, the Campo Santo at Pisa, and at the disused church of San Gregorio,

Venice, and proceeded to notice the church towers of Italy and France. In the former country the oldest form is the round tower, but the characteristic form is the campanile. In the North of Italy the campaniles, although not possessing any great variety, are as a rule of good proportion and bold in treatment, and show what may be done without the use of the buttress. In France we find the type of tower and spire with which we are not unfamiliar in this country. One of the best managed features of the French spires is the treatment of the broach and pinnacles. The low square tower with which we in this country are acquainted, does not seem to find a place in Italy or France. He could but just allude to the charming colour decoration, which adorns so many Italian churches, and to the use for these purposes of such a durable material as the mosaics, which have for so many centuries withstood the ravages of time, and remain to-day the most beautiful specimens of permanent decoration which it is possible to employ. In conclusion, Mr. Pratt said: One cannot return from scenes so delightful and work so interesting, without having gathered some lessons. From Italian brickwork we have especially much to learn: some of its detail is most exquisite, and it seems surprising that our own great brick country should attempt comparatively so little out of the ordinary way. That we cannot adopt the use of marble is perhaps an advantage; for the many systems of incrustation, which such a valuable material necessitates, would introduce a kind of construction not to be commended. In many respects the Italian work displays a simplicity of parts, and consequent largeness of scale, which detracts from its excellence. Their groined buildings bear no comparison with those of England and France, and their carving is disappointing. I refer particularly to capitals, and it seems strange that in a country noted for its figure sculpture, and where the column is so largely employed, we should see such poverty of treatment. Another Italian feature which is not satisfactory is the favourite adoption of a front or façade instead of a good all-round exterior. We see plenty of this in our modern work at home, but no one except the stingy client upholds the shabby-back style. In our churches we pay perhaps more attention to the exterior; the Italian usually reverses the order, and in this each has something to learn from the other. One might easily prolong comparisons, for a tour on the Continent opens one's eyes to varieties, defects, and beauties in different countries. May we profit by international intercourse, for while it will tend to develop our minds and will influence our lives, it will be the means of promoting the happiness and well-being of our fellow-men.

Mr. R. P. SPIERS suggested that it was scarcely prudent for Mr. Pratt to have endeavoured to describe a tour of eight months' duration in an hour's lecture; it was probable that he had materials for a second and more detailed lecture on some portion of his travels. In examining the domes of St. Front, at Perigueux, it was clear that it followed the general proportions of St. Mark's, Venice, but the construction was more clumsy and based on a different treatment of the vaults, the pendentives forming a kind of web. The restoration of this church had been unfortunately carried out, for it had completely blotted out one of the most important features of its history. Originally the arches in the nave of St. Front were scarcely perceptibly pointed; and M. Abadie, the architect who had restored it, had conceived the idea of making all the arches semi-circular; so he had the arcades carefully rebuilt in that manner, thus destroying their true character. The Abbey at Moissac was carefully measured and drawn during 1874-5 by Mr. Drinkwater, who was employed in Mr. Street's office. He would propose a vote of thanks to Mr. Pratt for his paper.

Mr. HUGH STANNUS, in seconding the motion, illustrated on the blackboard some of the subtle refinements in the planning, vaulting, and lighting of Italian churches, which appeared to have escaped Mr. Pratt's attention. He suggested that the lecture would have been valuable had it dealt with a few points in greater detail.

Mr. S. F. CLARKSON remarked that he was present at the International Congress of Architects, at Paris, last year, when M. Abadie was taken to task for his work of destructive restoration at Perigueux. He pleaded that when he

was called in, St. Front was so near absolute ruin that it became a question whether it should be maintained or not. He decided to repair rather than rebuild, and considered he was justified in restoring it to what he supposed was its original condition.

Mr. E. B. P'ANSON thought the extreme ingenuity displayed in the planning of Venetian churches would repay the study of those who might have to build in London streets or other confined spaces. Frequently, by a mere parallelogram they were skilfully broken up into aisles, chapels, and transepts, so as to produce the impression of considerable complexity and size. The brickwork of North Italy was the finest in the world, and while our treatment of brick was improving it would be better for students to broadly examine the mode in which it was used there than to take little bits cribbed from Walthamstowe, Stoke Newington, and Clapham, and endeavour from these to produce Queen Anne work.

Mr. BLASHILL urged upon young members not to confine their studies to England, but to take the first opportunity that availed of seeing how things architectural are managed on the Continent.

The vote of thanks having been carried, it was briefly responded to by Mr. Pratt.

ELECTION OF OFFICERS.

The scrutineers, Messrs. Farrow and Cresswell, announced that the following officers had been elected to serve during the session 1879-80:—President: S. Flint Clarkson. Vice-presidents: E. G. Hayes and R. E. Pownall. Members of Committee: A. Payne, W. H. Nash, E. B. P'Anson, T. E. Colclutt, J. Neale, A. Conder, G. R. Redgrave, E. E. Deane, H. L. Florence, and W. Penstone. Treasurer: J. Douglass Mathews. Librarian: H. W. Pratt. Secretaries: R. C. Page and F. Eales. Solicitor: Francis Truefitt. Assistant-librarians: J. W. Stone and F. Hemmings. Auditors: T. E. Mundy and W. Crisp. Registrar: Thomas H. Watson.

Mr. SPIERS proposed a vote of thanks to the President for his conduct in the chair during the session. Mr. Florence had been most regular in attendance at sessional meetings, and on committees had been assiduous in promoting the interests and prestige of the Association, and had upheld the position of president in the manner in which they all expected he would do so.

The motion was seconded by Mr. Blashill in complimentary terms, carried amidst applause, and suitably acknowledged by Mr. Florence.

THE YORKSHIRE FINE ART AND INDUSTRIAL EXHIBITION.

STAINED and painted glass is here of all descriptions—ecclesiastical, municipal, and domestic, Mediaeval and Renaissance, pictorial and conventional, quiet and glaring. The exhibitors are Messrs. Adam and Small, Glasgow; Campbell and Smith, London; Camm Bros., Birmingham; Dixon and Vasey, London; Gibbs and Howard, London; A. Hodgson, York; J. W. Knowles, York; Knowles and Co., London; Powell Bros., Leeds; Shrigley and Hunt, Lancaster; and Thomson and Co., Leeds. Powell Bros. occupy one of the positions above the refreshment bars. One light is fitted with a rather powerfully drawn figure of St. Dominic, in brown coat; simplicity of colour and outline has been aimed at with good result. The next light illustrates the Crucifixion, and is a portion of the east window of Nether-hoy Church. The third is less ecclesiastical, and illustrates the game of football. All three lights have grounds of white and yellow, the primary colours are well subdued, and the general effect is good. Messrs. Shrigley and Hunt have but one specimen of their art, Renaissance in style, illustrative of the Arts, with figures of Michael Angelo, Giorgione, Raphael, and Titian, with smaller figures above representing Poetry, Painting, and Sculpture, and one below, Music. The whole is pleasing in composition and colour. Next to this is a window by Messrs. Knowles and Co., of composite character, the various portions not only lacking unity in design, but being of various periods of Gothic art. The subjects are Christ Sitting in Glory, the Virgin and Child, St. Catherine of Alexandria, St. John the Evangelist, &c. Apparently they are not intended for one window. The exhibits of Messrs. Adam and Small are rather numerous, and are scattered

about different parts of the building. Under the north gallery are two lights, the one containing the figures of Eli and Samuel, the other Timothy and his Mother. These are excellently drawn and richly coloured, but the contrasts of colour are too marked. The draperies are very dark, inclining to opacity, while the heads and hands seem washed out in comparison. Still these windows bear a good deal of looking at, which is more than can be said of others very near them. By the north-west staircase the same firm has a pointed light, treated in less conventional manner, illustrating the text, "Praise the Lord, O my soul." A female stands in a posture of reverent attention, in front of her being a child, who looks up admiringly into her face. The plants in the background are rather coarse, but the whole is very pleasing, and rich in colour. There are several panels for domestic use in staircase and library windows, &c. One is composed of small squares of coarse glass, with a few of wavy glass at regular intervals, inclosed in a frame of Jacobean character, with rather absurd architectural details at top and bottom. There are other panels in English Renaissance, with stained and painted glass mixed. The exhibits of Messrs. Campbell and Smith are of domestic character, and are mostly panels for insertion in large light openings. "Autumn," "Morning," "Vivien and Merlin," "The Crow and the Pitcher," &c., form the subjects of these designs. Some of them seem too conventional. Messrs. Camm Bros. send a variety of work. One window tells the story of the Ten Virgins, the centre light being occupied by a figure of the Saviour regally attired. Another window is intended for a boudoir, and has small painted panels illustrating the "Midsummer Night's Dream." It is placed too high to be properly inspected. On the south-west stairs is another work of Messrs. Campbell and Smith. It is a panel with a scene from Moliere's "Bourgeois Gentilhomme," and shows how a subject may be freely treated and yet lend itself to the lines of the lead glazing, which hardly interfere with the effect, although the scale of the drawing is small. The colours are quiet and yet rich.

Messrs. Gibbs and Howard are represented by three windows, of which the largest is in a rococo Renaissance style—that is, the architectural details partake of that character. The central subject, "The Expulsion of the Moneychangers from the Temple," is vigorously treated. The flesh tints are browner than is usual in stained glass, and the modelling of the features, &c., better. Another light gives a picture of St. Balba, with an architectural model in her hand, under an elaborate Late Gothic canopy. The third exhibit shows Othello relating the story of his life, in which the artist has hardly done justice to Desdemona. The exhibits of Messrs. Thomason and Co. are all pleasing in tone, but there should be a little more variety about flesh tints when they are in immediate juxtaposition with white draperies. Messrs. Dixon have a window of two lights of very peculiar appearance, all the glass usually white having a dirty greenish tinge, while some of the draperies are very dark. The subject is the "Adoration of the Magi." The drawing is good, and the forms are well defined. Elsewhere this firm has three lights for a Tudor window, "St. Cecilia," with an angel on each side. There are some faults of drawing, as, e.g., the hands are rather small; but the arrangements of colours are pleasing. A panel for a staircase window has some forcible drawing and rich colour in a branch of some tree in blossom, with a ruby-coloured bird on the wing. In a circular panel representing the Entombment the colours are very dark, inclining to black. Altogether there is a very complete collection of stained and painted glass in this exhibition. It seems a pity that it could not have been kept more together, and, in several instances, nearer the eye of the observer.

C. P. E.

PRESERVED AND UNPRESERVED TIMBER.

THERE appears to be a general consensus of professional opinion as to the value of the preservation of timber for structural purposes, though a few architects and engineers are to be found who look upon all processes with distrust, and who, upon plausible grounds and with well-meaning intentions, declare certain processes to be useless or destructive under certain conditions. We are not about to discuss this general ques-

tion, which will be found to be a much narrower one when stripped of all ambiguities of meaning, and when that rock to all disputants, "seasoning," is disposed of; nor need we enter into the numerous processes that have been suggested, all pretty well known to our practical readers. We may confine the attention to one process, which all have agreed to accept as the most economical, namely, creosoting, while we refer to some information compiled by Mr. John Bogart, a member of the American Society of Civil Engineers, and published in a tabulated form in the January number of that Society's *Journal*. It will be admitted that no experience with respect to timber has been so great as that in connection with railways. Our permanent ways have given opportunities in the testing of timber and iron for a series of years not found elsewhere, and in no condition is timber more exposed to decay, or placed under more trying circumstances, than when it is laid as railroad sleepers, sometimes underground and at other times half-exposed to atmospheric influences. Accordingly, we find that railway engineers have devoted considerable attention to the preservation from decay of so important an item in the maintenance of railroads, and that for some years past the greatest care has been bestowed in collecting statistics. Mr. John Bogart, in his elaborate paper on the "Permanent Way of Railways in Great Britain, with especial reference to the Use of Timber Preserved and Unpreserved," has taken the trouble of collecting answers to a series of questions he circulated among the leading engineers of railways in Great Britain and Ireland. These he has given in a summarised form, and they are so valuable in their bearing upon the subject that we may briefly make a few remarks upon them. We find that the bulk of the sleepers used in English and Scotch railways are of Baltic red wood, generally about 9ft. long, 16in. by 5in. in section. All the railway officials who have given answers, with one exception, record the process of creosoting as the method that has proved the most efficacious. Among the names of engineers who have supplied information, we find Mr. R. Johnson, of the Great Northern; Mr. E. H. Lloyd, of the Great Western; Mr. Alfred A. Langley, of the Great Eastern; Mr. W. Jacob, of the London and South Western; Mr. H. Johnston, of the Midland, and several others. The process is the only one now in general use, and the amount of creosote oil forced into the wood averages 0.82 gallons per cubic foot, or the weight of oil forced in averages about 7.175lb. per cubic foot. In many cases the work is done by contract, in others the company has its own creosoting works. The cost averages about 10d. a sleeper. As regards the average life of preserved sleepers, the answers are very various. Some give it as 10 years, others 20, but taking all the replies, 16 years seems to be the general average, while the actual gain by the process is stated to be from two to ten years. In reply to the question whether preserved sleepers hold the spike better than unpreserved ones, the majority of answers goes to show that they do; though, as far as compressibility is concerned, the experience of many is, that creosoting does not harden the wood so much as to prevent the chair cutting under heavy traffic. The writer mentions several samples of sleepers taken from roadways which are in an excellent state of preservation after a service of 10 to 22 years. We have already quoted the experience obtained by the officials of the North-Eastern Railway, and another sample of a creosoted Scotch fir sleeper taken promiscuously out of the main line near Tweedmouth, having been in use 20 years, is mentioned in such a good condition that the engineer, Mr. Harrison, considers it to be likely to wear another 10 years, though it has been run over during that period by all passenger and goods trains between London and Edinburgh.

Mr. Bogart's researches and summarised results prove the value of creosote oil as a preservative in railway works, and we consider the experiment one well worth the attention of engineers and architects. If one of the professional institutions would commence a series of tests with the object of showing the value of preservative processes, beginning with paint, and applying the other chief processes to timbers placed in various positions, and recording the condition of each specimen after a given interval, something like certainty would be attained. Timber piles exposed to the joint influence of water and air, posts for fencing, and pillars

standing above ground, are three cases whose conditions are somewhat different; these should be all tried. Timbers in exposed positions laid horizontally, weather boarding, rafters, and joists, should be tested in several different circumstances, both as regards exposure and the seasoning of the timber. It would be well if each institution had a record office to which particulars and statistics of this sort could be forwarded, so that the results may be classified and compared for practical reference.

PARLIAMENTARY NOTES.

ARTISANS' DWELLINGS IN PRIVATE BURYING GROUNDS.—Mr. Waddy read a statement in the House of Commons on Thursday week relative to excavations which had been made in a private burying-ground, as he understood, in Islington, which had been utilised as a site for artisans' houses, under the Act of 1868. After digging for not more than a foot in depth the workmen came upon a mass of human bones and black slush. To enable them to continue their operations they were supplied with stimulants, but no sufficient foundation could be prepared for the building. The ground was loaded with human remains and dangerous to the public health. He wished to know whether anything could be done to prevent houses being erected in such a locality, and if erected, to prevent them being occupied.—Mr. Cross was anxious to have made an order to close the place and cover it up; but he found on inquiry it would be impossible to do so. The same thing had been attempted by his predecessor Sir George Grey, but he had no power to interfere. Perhaps the best remedy in such a case would be to indict the owner of the private burial-ground or the builders for a nuisance. He had ordered a special report to be made to him. He could not conceive anything more injurious or more scandalous.

THE WEAVERS TOWER AT NEWCASTLE.—Mr. Percy Wyndham, on Tuesday, asked the Secretary to the Treasury whether, in the matter of the threatened destruction of the Weavers Tower at Newcastle, the Lords of the Treasury had stated their opinion that its destruction ought not to occur except upon the decision of a clear majority of the whole number of the council; whether he was aware that the motion for its destruction had been carried by a majority of one of the whole number of the council; and whether in the circumstances the Lords of the Treasury would not again interfere. Sir H. Selwin-Ibbetson said,—The Lords of the Treasury did express an opinion that the destruction of the building should not occur except upon the decision of a clear majority of the whole number of the Town Council. I am informed by the Town Clerk that the council when fully constituted consists of 64 members. When the discussion was held about the Weavers Tower there were two vacancies, reducing the numbers to 62. Of these 48 were present at the meeting, 32 voted for the destruction, 6 against, and 10 declined to vote. The Treasury has no power to interfere further in the matter, as it has already signified its assent to the scheme for the free library subject to a recommendation that the question of preserving the tower should be decided only by a clear majority of the council. As only 6 members out of 62 were found to vote for the preservation the division must be regarded as a decisive expression of local opinion, and I believe I may say that the principal opponent expressed himself satisfied with the decision come to at the last meeting.

At the half-yearly meeting of the proprietors of the Bank of Ireland Stock, held in the old House of Lords, Dublin, on Friday, the chairman called attention to the fact that the room has been newly painted, decorated, and furnished, and the historical tapestries have been restored to a proper condition. These tapestries were made in the liberties of Dublin in the year 1732 by John Van Beaver, a Huguenot refugee, and bear his signature and the date. In the following year they were hung in the place they now occupy. Being in a very dilapidated state, and almost falling to pieces, they were recently sent for repair to the Royal Tapestry Works at Windsor, where the restorations have been carefully effected.

The local board of Torquay have instructed their surveyor to prepare plans for a fever hospital, the cost of which is not to exceed £2,000. They have also decided to make the town supply of water constant instead of intermittent, as hitherto.

NEW PREMISES IN WATLING-STREET.—NEW PREMISES IN ROOD-LANE.—HOUSE AT DIDSBUY.—DESIGNS FOR LYCH GATE, ST. PETER'S, CARMARTHEN.—DESIGN FOR A VILLAGE SCHOOL CHAPEL.—ARCHITECTURAL MUSEUM SKETCHES.

OUR LITHOGRAPHIC ILLUSTRATIONS.

NEW BUSINESS PREMISES IN THE CITY.

A DOUBLE-PAGE illustration shows perspectives of new premises at the junction of Watling and Broad-streets (on the site till recently occupied by the Church of All Hallows, in which John Milton was baptised), and in Rood-lane. They have been recently erected, from the designs of Mr. Alexander Peebles, F.R.I.B.A., of Salter's-hall-court, Cannon-street, E.C.

HOUSE AND STABLES AT DIDSBUY, NEAR MANCHESTER.

THE view we give of this house is of the front facing the Mersey-road, the principal elevation being towards the gardens. The whole of the external walls from the ground-floor line are to be covered with Portland cement, finished with silicate distemper a toned white, the quoins, cornices, strings, chimneys, &c., being of bright red brick, and the roofs green slates of a small size. We give the ground-plan. On the first floor there are four large bedrooms, nursery, and bath-room, &c., and on the floor above the same number of bedrooms, all square to the ceiling, a servant's bath-room being provided off the half-landing of back-stairs. A range of conservatories will connect the house and stables, and a large brick wall, with close gateway, inclose the whole of this side of the site as shown in the view. Mr. Geo. Frooth Roper, of Haworth's-buildings, Manchester, is the architect.

LYCH GATE, CARMARTHEN.

AMONG our lithographic plates to-day we illustrate both the selected and second design for the lych gate which is about to be erected at St. Peter's Church, Carmarthen, in memory of the late vicar, the Rev. Latimer Maurice Jones. The designs were submitted in open competition last November, with about thirty others, and the selection was made upon the recommendation of the Bishop of St. David's. The author of the selected design is Mr. Francis E. Jones, architect, of 29, Cockspur-street, S.W., and the contractor for the work is Mr. Thomas David, builder, of St. Clear's, near Carmarthen. The

lych gate will be of Runcorn's stone throughout, the roof being of stone to give a monumental or a "memorial character" to the structure, as suggested in the instructions. The second design is the work of Mr. J. Martin Brooks, of Wellington-street, Strand, who has failed to send us any particulars of his plan. However, our readers may compare the two designs, and draw their own conclusions. Mr. Brooks' drawing is now on view at the Royal Academy's Exhibition.

ROYAL ARCHITECTURAL MUSEUM SKETCHING CLUB.—SKETCHES OF ORNAMENT FROM SALISBURY, &c.

THE lithographic illustration of ornamental detail which we publish to-day is from the full-size sketches by Mr. Pennington made at the Museum in March last. The enriched moulding is from the Audley Chapel, Salisbury Cathedral, and the beautifully-designed patera from a ceiling in a cast in the Museum bearing no date or name.

"BUILDING NEWS" DESIGNING CLUB. A VILLAGE SCHOOL-CHAPEL.

A VILLAGE SCHOOL-CHAPEL is one of the most ordinary as well as useful subjects, perhaps, that could have been chosen for the members of our Designing Club on which to exercise their ingenuity, and in consequence an unusually large number of designs were submitted. Several took rather the form of a cemetery chapel or country church, while others assumed more of the village mixed school character. Few designs combined the twofold requirements of a school-chapel, either in plan or architectural expression. "S in a circle," whose design we publish to-day, unquestionably worked out the problem with the most satisfactory results. His plan, upon which we have already remarked when reviewing the whole series, has many points of merit, especially in the double-porch or lobby, and in the separate chancel arrangement, without making the chancel too prominent or expensive a feature.

THE ARCHITECTURAL MUSEUM SKETCHING-CLUB AT STONE, KENT.

LAST Saturday several members of this sketching club joined the first out-door sketching excursion which has been held in connection with the museum, it being proposed to hold a short series of similar outings to places in the neighbourhood of London during the summer. Leaving Charing Cross by half-past two, the excursionists reached Stone Church, the building selected for the day's sketching, rather before four, the party numbering about a dozen members. A general survey of the church was made, and some brief particulars being given by the conductor of the party, Mr. Maurice B. Adams, after which sketches were made from various portions, and general views from almost every side, each individual simply following his own bent. Of course the interior is deservingly considered by far the most interesting portion of the church, though the building is exceedingly picturesque from the north-east, where the quaint though Late chapel of the Wylshyre family, now used as an organ-chamber, breaks up the composition with the flying buttress to the chancel wall over the embattled parapet of the chapel below, while the roof of the chancel, being higher than the nave, adds greatly to the effect. The church consists simply of a chancel and nave, with north and south aisles and western tower, the main entrance being from the north side through an elaborate and curiously enriched doorway, the mouldings of which are much dilapidated. The nave arcade is of three bays of thirteenth-century date, having beautifully foliated eaps, unsurpassed, perhaps, by any in the kingdom. The windows of the aisles are composed of two splayed equilateral lights with a quatrefoil spandrel; but the easternmost ones in either aisle seem to have been the only ones really completed in accordance with the original design, and these are exquisite in proportion, having a detached shaft and inner tracery head. The roof, which is modern, is of wood, and no traces of a groined roof remain. The chancel is enriched on all three sides by an elaborate wall arcade, the details of which are familiar to all English students of Gothic work, and perhaps no example has been more frequently measured and drawn. The windows of the chancel, as well as the groined roof, are restorations, or, at any rate, the groining may be so termed, though the insertion of the Geometrical windows appears

more questionable, not as to date, for they were inserted a few years ago by Mr. G. E. Street, when he repaired the church, but in design and fitness. Perpendicular windows existed before Mr. Street took the work in hand, and these have been removed to make way for the new ones of earlier design, the window on the south side being of the same size and detail as that in the east wall, so that when seen from the exterior the scale of the windows in the nave suffers seriously on this account. In 1778 the chancel is said to have been furnished with stalls of ancient date, however, these were removed before 1836. At present some ordinary seats are used. The benches in the nave are of deal, with ends well notched, arched, and chamfered. The pulpit, with the exception of the crowning cornice, is very poor both in execution and design. The windows at the east end of the aisles are of different design; that in the north aisle is by far the larger of the two, and is very handsome, though the window, as a whole, seems of an indifferent proportion. Mr. Street has carefully restored it, leaving the upper part open to the organ-chamber. The window in the south aisle east wall is more simple, though more in keeping with the side lights, and certainly of finer proportion than the larger window just named. The tower is later in style than the nave and lower portion, while it appears to be of a much meaner character than that originally intended, judging from the two flying buttresses in the aisles, springing from the wall at window-sill level to the top of the piers under the tower, as this precaution would, probably, not be necessary had so small a tower only have been proposed. The eaps of the tower piers are unsatisfactory in the abacus. The stair-turret is quaintly arranged, and the curious way in which the clock comes in the corner of the south side, over the turret, is characteristically picturesque. The windows of the vestibule at the west end of the aisle are of Decorated character of simple design, as is the west doorway. The church and churchyard are well kept, and Canon Murray is the rector. The dedication is to St. Mary, and the living is in the gift of the Bishop of Rochester. Walter de Morton, a bishop of that see, is supposed to have built the nave and chancel, commencing the work in about 1270. Mr. Street is of the opinion that the architect of the building was also the designer of Westminster Abbey. Daniel Dig, the first rector, was presented to the living in 1284, the 13th year of the reign of Edward the First, by the Bishop of Rochester. The living is said to be valued at £765 per annum.

CHIPS.

At a meeting of the Royal Dublin Society held on Monday evening Mr. G. H. Kinahan, M.R.I.A., read a paper on Arklow Harbour, the improvement of which was commenced in 1847. He stated that though the money expended on it, including £30,000 by the Wicklow Copper Mine Co., had given results far short of those anticipated, yet the port had been vastly improved; for while in old days it only admitted boats drawing from 3ft. to 4ft. of water, now most of the vessels that frequented it drew from 8ft. to 10ft., and even more. He made various suggestions for the further improvement of the harbour. In the course of the subsequent discussion, it was stated that the Wicklow Copper Mine Co. are expending £40 a week on the improvement of the harbour.

An additional supply of water from Moorfoots for Edinburgh was turned on by the Lord Provost on Friday. The works are so far completed as to supply 4,000,000 gallons of water daily, but when finished the total daily water supply will be double that given hitherto.

On Sunday week All Saints' Roman Catholic Church at Sedgley was reopened after alteration. The building has been repewed and refloored and decorated in colour at a cost of £200. The work has been carried out by Mr. Hilton, builder, and Mr. Eggington, painter, of Sedgley.

Mr. Folingsby, an Englishman who has resided for many years at Munich, has been appointed director of the Melbourne Art Academy.

The Lords Commissioners of the Admiralty have accepted the tender of Mr. J. G. Naylar, of Rochester, amounting to £3,443, for the erection of new schools, with teacher's residence, for the education of the children of the Royal Marines who may be stationed in the Chatham district. The foundations of the buildings have already been put in by the Admiralty, who also supply bricks and stonework for the building, bringing the total cost to upwards of £5,000.

THE "BUILDING NEWS" DESIGNING CLUB.

DESIGNS FOR A SMALL STABLE.

THIS subject has been well taken up, and a few skilful designs have been sent in. "S" in circle, which we place first, is meritorious in plan, and exhibits a knowledge of the requirements of stable building; in the elevation also the author has shown a considerable disengagement in the treatment of a structure of this class. The stable, 23ft. by 15ft. wide, has two stalls, each 6ft. in clear, and a loose box 15ft. by 11ft. at one end. The coach-house and coachman's rooms form a separate and parallel block, connected to the stable by a harness-room, which is well placed, with a washing-space for horses in front. The width of stable is narrow; 18ft. is not too much. We find that the author has observed a few necessary points, such as that the stable-door should open outwards, and that the hay-shoot and ladder should be placed out of sight of the horses; the former is brought down a shaft in the wall, at the back of the horses. The drains are well shown, but we see no provision for storage nor means of ventilation. Walls of stable, &c., are proposed to be cemented. The windows are small, and do not open at the top, as they ought to do, but otherwise the treatment is characteristic. "Motto J" is an exceedingly simple and picturesque elevation. The plan forms two ranges of building at right angles, the stalls occupying the corner, with a separate loose box adjoining. The carriage-house and harness-room, together with a gateway leading into the stable-yard, form the main elevation; these are conveniently placed, and a manure-store is formed at the end of stable-range. The author proposes stone walling, relieved by brown stone bands. The coachman's rooms and hayloft are placed above the arched gateway and carriage-house, and the former are lighted by projecting casements of wide proportions. The design, though appropriate in general arrangement, certainly affects the antiquated too much, and the windows are too small for effective ventilation. Why the iron girder over coach-house doorway and the heavy stone lintels? "Triangle in Circle" is more modern in spirit, and characteristic as regards elevation. The building is planned as one long range, with the loose box having a separate entrance at one end and the carriage-house at the other. The stable, 17ft. by 14ft., is well placed in relation to the harness-room; the corn-shoot is a four-flued trunk, set in the wall between stable and loose box, and the stove heating the harness-room is made to serve the coach-house, by being placed in an opening in the division wall. The stair to the coachman's room above harness-room is made a feature in the elevation, and is carried up as a pigeon-house. A timber roof (open) covers the coach-house, which has sliding doors and a shed in front for cleaning purposes. Brick walls with mullioned windows are shown, and the author has produced a design that expresses its purpose; but the drawing of the octagon turret in the sketch is a trifle twisty. "Noah" indulges in Queen Anne, and the buildings are made to form three sides of an inclosed paved yard, the entrance separating the dwelling from the stable range. We do not find much to object to, except that the plan is expensive and rather beyond the requirements we had in view. The harness-room is placed at the angle between the stable and coach-house, with a separate doorway into each. We do not like the corn-shoot at the side of the stall, but the hayloft above the harness-room and coach-house is better than a loft above the horses for sanitary reasons, and so is a stable open to roof. Cottam's fittings are proposed. The chief requirements are met. On the other hand, the coachman's house with four bedrooms is unnecessarily large. The walls are proposed to be executed in flint and red brick in the quoins, strings, and window dressing. The loft-windows are circular, and one of the grooms' bedrooms is made to project over the yard entrance with a pediment, and is constructed of timber framing and plaster. The treatment is in keeping, and the drawing creditable. There is much to commend in "No Hope," the author of which has studied extreme simplicity in the exterior, and has adopted a tile-hung upper story with red tile roof. The stalls are arranged one on each side of the loose box which occupies the corner, the harness-room and entrance lobby are conveniently placed, and a door is provided between the harness-room and

coach-house, which is 17ft. by 16ft. and has sliding doors. The living-rooms form another range at right angles, and the two buildings are pleasingly combined. Similar in plan and external design is "Maggie, alias Such a Dog." The stable, 18ft. by 17ft., has the loose box in the corner, as in the former case, but the coach-house is placed at the end of the dwelling range. There is little to find fault with in the position of the doorways and conveniences, but no drainage is indicated. The gables are timber-framed and the elevations are modest and unpretending. "Honey Dew" adopts the one-range plan, and we find the harness-room and coach-house are warmed by the same stove. Economy has been consulted in the construction and arrangement, the whole being contained under one roof. The elevations are neatly but mechanically drawn, suitable and expressive in character, though we take exception to the attenuated proportions of the gabled dormers and narrow windows. We fail to see the advantage of the cement facing to the outer walls. "Omega" is a compact plan, the stable, house, and stable-yard being inclosed within a square. The loose box is placed between the two stalls, the harness-room and washing lobby are conveniently near, and the former and living-room communicate by a doorway between the two rooms. The elevations are artistically treated in brick and tile, the details are plain and effective, and the whole design is creditably drawn. A less expensive plan, however, has "Enigma" for a motto; the stalls and loose boxes are arranged as in the last, but the coach-house and harness-room form one elevation, which is characteristic. The sanitary details are not shown. Treated with some taste, though the details of dormers are preposterously stilted, is "North-west," and we cannot discern the reason of confining the timber framing to the story above the coach-house. In a small stable we think the loose box is best combined with the stalls, instead of being made a distinct apartment. The house behind the coach-house, and without any communication with the stable, is not convenient. "Be to its Merits very Kind," &c., sends a number of carefully-prepared drawings and details. The stable and harness-room are in communication, but separated by a passage entrance with stairs to loft and bed-rooms; the doorway to the stable is too narrow, and the living and bed-rooms above is certainly a most objectionable position from a sanitary point of view, to say nothing of the difficulty of conveying the corn through zinc pipes of the inclination shown. The alternative plan is better, with the loft above the stalls. Sheringham's ventilators are shown to the stables, besides extracting shafts with Boyle's valves; but the author, prolific in details of the finishings to house, does not give any details of the stable fittings or windows. One of the elevations too much resembles a cottage. "Colorado Beetle": this is a rather long and expensive arrangement. It is not desirable to separate the loose box from the stalls, and the latter appear badly ventilated. The gables are rather fancifully filled in with herring-bone and timber-work, and the design is not wanting in merit. "Star in Circle" is inexpensive and compact in plan, but the corn and hay shoot are rather in the way of the entrance to stable, and there is no space for cleaning shown. With a little more time and study spent over the plan, and with a more carefully designed elevation, instead of the very one-sided and awkward gable over loft, the design would have stood higher. The author provides a foul-air shaft from stable through loft to a louver ventilating turret. "Ieh Dien" shows a fancy erection in brick and timber, with an outer stair to living-rooms above coach-house. The harness-room lobby is too cramped for washing; no fittings are shown. "Con Amore" is simple and pleasing as an elevation, but spoilt by the entrance to the stable, which is placed at the end, and is not convenient for the turning of horses; it would be very awkward to lead a horse into the loose box, for instance, and 4 feet cleaning space outside the stalls is insufficient. 5ft. 6in. is not wide enough between the stall boards. "Curiose" is too straggling in its plan. The stable and coach-house would be better closer together than divided by the gateway; there is no washing space, and the entrances to the stalls are not in the best positions. The coachman's dwelling is rather too prominent a feature for a small stable range, though the author

sends in a neatly-drawn and pleasing west front. We can only name the other designs we have received in the order of their merit. "J. C." in circle (clever but costly); "Cleo" (not economical, and undesirable in upper plan); "Sub Silentio" (not expressive, and entrance poor); "Nitor" (wanting compactness, and expensive in style); "Boz" (badly-planned harness-room); "East Anglian" (wasteful in space); "Ogmore" (stalls too narrow, and entrance poor); "I Strive" (expensive in style); "Ivanhoe" (entrance defective). Several other designs, though many showing careful plans and skilful drawings, fail in general suitability of design. Of these we note "Ad Valorem," "XL," "Maltese Cross," "C. W. D.," "Burswell," "Elève," "Veritas Vincit," "Stefano," "Melmotte," "Try," "Peter," "Belteshazzar," "Semper Paratus," "Tam O'Shanter," "Che Sara Sara," "Factable," "Amateur," "Operam Dare."

A SUMMER-HOUSE.

The design with "Colorado Beetle" as a motto, if it does not show a clever artistic working out, has certainly the most ingenious plan. It is a series of four alcoves, with seats forming a quatrefoil in plan, the hollows formed by the inner four angular seats forming three outer seats, the fourth side being taken up by the doorway. The framing is composed of upright angle studs filled with lights, the heads of which are trefoiled. A circular conical roof of heather is suggested, and the narrowest internal diameter is 10ft. In all, there are four alcove seats, and three single seats inside and three outside. "Motto J" is a quaintly-treated but well-drawn design in a species of Queen Anne. In plan it consists of a long-shaped room, with a seat round three sides; the front forms a flat projecting bay, with a step up at the entrance. Externally, the roof is thatched, and of plain span character; the windows are ranged as square small pane sashes round the top, the lower panels between uprights being filled with Lascelles concrete slabs plastered. The timbers 6in. by 6in. are proposed to be painted peacock blue. The plan lacks roominess, and the design is more suggestive of a porch than a summer-house. "Jack" is another cleverly-drawn design, in an Anglo-Japanese style, square in plan, with an alcove or bayed seat on one side, and surrounding seats. At the angles are store cupboards for keeping refreshments and utensils. In the centre of one side is a small fireplace for stove. The sides have sliding sashes, with stained-glass lights above, forming frieze panel, and the roof is of shingles of pyramidal form, with a wrought finial or a louvered ventilator at the apex. A greenish-blue is suggested for the external painting, and lead-lights for the windows. The drawing is somewhat confused with unnecessary constructive lines. Inside, a lining of lath-and-plaster surrounds the lower part, the outer facing being grooved and tongued vertical weather boarding with filleted joints. We can only mention the other sketches in order of merit: "Noah," "Try," "Be to its Merits, &c.," "Truth shall Prevail," "Burswell," "Amateur," and "Ogmore."

CHIPS.

Another historical stained-glass window has been placed in the Guildhall at York. It commemorates the marching, in 1319, of Nicholas de Fleming, Mayor of York, at the head of the armed citizens, against the Scots. It has been designed by Mr. J. E. Doyle, of London, author of the "Chronicles of England," and executed by M. J. B. Capronnier, of Brussels.

An inquiry was held at Halstead, Essex, on the 6th inst., before Mr. Samuel J. Smith, C.E., inspector to the Local Government Board, respecting an application from the Halstead Local Board for sanction to borrow £7,000 for works of sewerage and sewage disposal. The scheme has been prepared by Mr. Bailey Denton, C.E.

A stained-glass window has just been placed in St. Mary's Church, Tadcaster. It is from the works of Mr. Constable, of Cambridge and London. The subjects are: in the centre, "Christ, the Good Shepherd," and in the side lights "John the Baptist Preaching in the Wilderness" and "Paul preaching at Athens."

On Monday afternoon the Macclesfield School of Art was opened. It has been erected at a cost of £5,500. The architect is Mr. James Stevens, F.R.I.B.A., of Manchester and Macclesfield. It is in the Gothic style, and is well lighted and ventilated.

COMPETITIONS.

CITY OF LONDON SCHOOL COMPETITION.—Nothing has transpired of any consequence since our last article. Though a question was put the other day to Mr. Felton, the chairman of the committee, asking whether the City of London School Committee could not now throw open to the public the plans, no satisfactory answer was given, but the chairman's reply was a remarkable one. He said the "committee had not felt themselves justified in throwing open the designs to the public. They belonged to the competitors, who had spent much trouble and pains on them, and without their leave it would be an injustice to them to exhibit the plans." A more absurd reason we have never heard before, as if competitors would not declare in favour of a public examination rather than one conducted with closed doors. No competitor would hesitate one moment to give access to the professional press; indeed, from what we have heard, the surprise is that the designs should have been kept so unpleasantly secret so long. As Mr. Edmeston said justly, it was quite unnecessary to seek consent of competitors, who were not likely to object. In our whole experience of competitions we certainly have never heard a more ridiculous excuse made, as committees who invite competition always reserve to themselves the right of exhibition. But there are certain rumours afloat that make the excuse more intelligible. From an inquiry made at the secretary's office, we hear the report of the committee is to be printed and distributed at the next meeting of the Court of Common Council. This looks as if it were meant that the public, even when they have the chance of criticising, shall not alter the decision.

WOLVERHAMPTON PROPOSED PUBLIC PARK.—On Friday a special meeting of the Wolverhampton Corporation was held for the purpose of receiving the report, which according to instructions had been drawn up by the borough surveyor, Mr. G. E. Thoms, on the twenty-seven designs, sent in by competitors for the laying out of the proposed public park. After considering the report and examining the whole of the plans (the meeting occupying three hours) three of the designs bearing the mottoes "Al Fresco," "Fortuna Sequitur," and "Spe Labor Levis," were selected as the best. "Al Fresco's" design provides a boating lake, a lake for aquatic fowl, recreation ground for girls, gymnasium for boys, volunteer drill and general recreation ground, and archery and bowling greens. The plans of "Fortuna Sequitur" intend the laying out of the site for a drill ground, a cricket field, lakes, archery, and bowling greens, and numerous small patches of lawn with flower borders. "Spe Labor Levis" designs ornamental lakes, cricket, volunteer drill, and archery grounds, bowling green and flower gardens. The borough surveyor was instructed to report again on three selected designs to another meeting of the committee, when the final decision will be made as to the best two, and the letters containing competitors' names opened. Premiums of £50 and £25 are offered for the first and second designs.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

ROMAN VILLA NEAR BOGNOR.—Mr. Hale White writes to the *Athenæum*:—"About a couple of miles west of Amberley Station, on the London and Brighton Railway, near the village of Bognor and the old Roman road from Chichester, lie the remains of a large Roman villa. I am not an antiquary, and cannot profess to describe them, but, according to the guide-books, they are as remarkable as any in England. Anyhow, they are of singular beauty, and most interesting to anybody with the smallest acquaintance with the history of England. The proprietor of the land on which they lie—a small farmer—has done his best to protect them from the weather by building rough huts over them; but during the last winter the pavement has suffered severely, the frost having broken up the ground beneath. Can nothing be done to preserve them? They ought not to be put in the British Museum, for, if removed, the impression of the grandeur and size of the house, of which they are a part, would be altogether lost. We should lose, too, the old Roman's appreciation of landscape, for a lovelier sight could hardly be found in Sussex. We can do a great deal with money; we can build

great palaces and cathedrals which cost hundreds of thousands of pounds, but there is one thing which millions cannot do—we cannot bring back again so much as one square yard of that perfect work, exemplary for generations of builders and architects, which is going to ruin in the Bognor fields if once we are foolish enough to let it decay.

MIDLAND INSTITUTE.—The first excursion of the archaeological section of the Birmingham Midland Institute took place on Monday last. "Tamworth Tower and Town" were first visited. The castle is said to have been founded by Ethelfleda, the widow of Ethelred, Earl of Mercia. The Saxon castle having been destroyed by the Danes or Normans, a new castle was built in the reign of Henry I., by Sir Roger Marmon, on a much more extensive scale. Although it cannot be proved that a single fragment of the original walling remains, there are good grounds for believing that the lower part of the curtain wall, of herring-bone masonry, which now supports the path across the ditch to the entrance, is the work of Ethelfleda, and it is also possible that some fragments of the original outer wall remain near the ground. Be this as it may, it is certain that large portions of the Norman wall remain, but it has been so patched and repaired, and is so much hidden by ivy, that it is impossible to say how much. Of the outer wards and works of the Norman period not a vestige is visible. Within the present great outer wall—three yards thick—are the inhabited rooms of the existing building. These are all of much later date, the oldest parts—the hall, kitchen, and dining-room—being probably of the time of Henry VIII. Large additions were made in the time of James the First, and still later. After luncheon at the castle, the party proceeded in carriages to Staffeld, where the curious little disused chapel was examined. It contains some curious recumbent effigies and many mural monuments; the old oak benches and wood screen remain, and a quaint seventeenth-century pulpit and sounding-board, but all covered with dust. In the east window is some interesting old glass, probably Flemish. This was put into its present position only a few years ago. The building has a western doorway, door, and lock, all of which were pronounced to be of the twelfth century, but the greater part of the building is of the fourteenth century date. The party next went on to Clifton Campville, and examined the church. The building is throughout of nearly one date, the fourteenth century. There are, however, portions of the chancel about one hundred years earlier. Elford, about five miles from Tamworth, was next visited, and after tea the party went to the church, which has been rebuilt, all but the tower, by Mr. Salvin and Mr. Street.

NORTHERN ARCHITECTURAL ASSOCIATION.—The annual meeting of the above association was held on Tuesday evening at Newcastle-on-Tyne, when the retiring president, Mr. T. Oliver, delivered his address. Touching on ecclesiastical architecture, he said—"It is not necessary that our churches should be identical, either in architecture or in ritual: they should represent, I think, the variety of man's religious convictions, feelings, and requirements, while, at the same time, they should unmistakably represent the oneness of all true religion. It is not with any degree of regret that I perceive in the 'new departure' from the Gothic of Pugin and Scott, the sign of an active living art; for just as it was considered perfect in the fourteenth century, and it passed away, so is it now. Shall it be superseded by Perpendicular Gothic, Romanesque, or the Italian Renaissance? All architecture has been engrafted. As stone took the place of wood, and the rock-cut temples the place of dismal caves, imperceptible architecture reared its inexplicable and beautiful forms, first upon one civilisation and religion, then upon another, until it culminated in Christian Italian and Mediæval Gothic. Those imbued with the like spirit that inspired our predecessors, may select and combine, and in so doing produce a new and harmonious style of architecture more particularly adapted to our age and to our wants." Mr. Oliver then referred at some length to the question of the Free Library and the Weavers' Tower; and on the subject of plans, he said if the matter had been put to competition, he had no hesitation in saying that they might have had a design worthy of a town like Newcastle. "It is to be hoped," he continued, "that if the Carlisle Tower should be removed, the ridiculous

ideas of transferring it or recording it by marble mosses, or engraving a plate like a coffin plate, will be abandoned. If it must go, let it go, and bury the bad feeling along with it. But if it can be saved, by all means let it be done."

CHIPS.

On Tuesday week the Archbishop of York reopened the fine Church of St. Peter, Pickering, after restoration at a cost of £7,000. The works have included the rebuilding of transepts, which are all Early English period, the reseating and decoration of nave, taking out and renewing the foundations of the fine Roman tower, which had been much damaged by weather, re-roofing the chancel with Riga oak, and opening out an ancient chapel in chancel. During the restoration three fine piscinas and several lancet windows were found walled up in the chancel, as well as a magnificent fresco of the "Lord's Supper"; there were also discovered in the chancel some effigies of the Lascelles, the de Gaunt, and the de Brus families. Five memorial stained-glass windows have been placed in the church, and in the tower a public clock has been erected at a cost of £150. Mr. J. S. Crowther, of Manchester, was the architect for the restoration.

The foundation-stone of a new Roman Catholic school was laid at Thetford, Norfolk, on Tuesday week. Mr. J. B. Pearce, of Norwich, is the architect, and Messrs. Hubbard, of Dereham, are the contractors.

The parish church of Moor Monkton, near York, was reopened on Wednesday week, after complete restoration at a cost of £1,600.

The Scarborough town council have appointed Mr. W. Millhouse, of Leeds, as draughtsman in the borough surveyor's office. There were 89 applications for the post, to which is attached a salary of £175 per annum.

A new organ was opened at Castle Heddingham Church, North Essex, last week. The builders are Messrs. Walker and Son, of Francis-street, W. The organ contains two complete manuals and a pedal-organ, and cost £325. The casing is of simple character, stained, the front speaking-pipes being decorated.

The new market halls at Holywell were opened on Tuesday week. They consist of a parallelogram, 65ft., by 45ft. for vegetable market, with brickwork walls, covered with a roof of wrought-iron principals, with pitch-pine boarding under slates, in two spans, supported by a row of columns; and of a butchers' market, 69ft. by 48ft., constructed in a similar manner. A town hall to be hereafter built in front is part of the scheme. Messrs. Scrivener and Sons, of Hanley, Staffordshire, are the architects, and Messrs. Thomas Hughes and Son, of Holywell, the contractors.

The town council of Reading have decided to commence forthwith the construction of the new town hall, free library, museum, and schools of science, to be built adjoining the present town hall, in Blagrove-street.

A new memorial clock has been placed in the tower of All Saints' Church, Parleigh, Essex. It has been manufactured by Mr. J. W. Benson, of London. The frame is of cast-iron fitted with runner blocks to facilitate cleansing; the escapement is Graham's improved dead beat, and the clock strikes the hours on the tenor bell on the rack repeating principle. The time is shown on two dials of copper 4ft. diameter, painted black with gilt figures and hands.

An institute and cocoa-house, including public room, lecture-room, and library, is about to be built at Brymbo, near Wrexham. Mr. H. A. W. Robertson, of Penrhos, Brymbo, is the architect.

The West Kent Main Sewerage Bill has been read a third time, and passed in the House of Commons.

The convocation of Oxford University decided last week, after a division, to let ten acres of University Park as a cricket ground, and to erect a pavilion thereon at an expense not exceeding £2,000.

The memorial stone of a new Congregational church was laid at Aberdovey on Tuesday week; it will seat 300 persons, and is to be built of limestone and granite.

Mr. John Hughes, of Llansannan, has been elected surveyor of the highways in the newly-formed district of Henllan, Llancfrydd, and Llansannan, at a salary of £60 a-year.

A new parish-room is in course of erection in Upper Cranfield-street, S.E., New Cross, in connection with St. Peter's Church. It is semi-Gothic in style, and in addition to a hall seating 400 persons, there are six class-rooms and the usual conveniences. Mr. J. O. Abbott is honorary architect, Messrs. Bann, Julian, and Co., of Southwark, are the contractors. The total cost of erection and furnishing is estimated at £3,000.

Building Intelligence.

—♦♦—

BOLSTERSTONE.—The parish church of Bolsterstone, Yorks, was reopened last week, after having undergone a thorough restoration. The whole of the work was not done at one time, the chancel and tower having been rebuilt in 1873, at a cost of £1,800. The rebuilding of the nave has only just been completed at a cost of £2,300. The building, which is of substantial proportions, is in the Early Pointed or 15th Century style of architecture. Its dimensions are—tower, 12ft. by 12ft.; nave, 43ft. by 24ft.; aisles, 43ft. by 12ft., and chancel, 31ft. by 20ft. The open seats are of pitch-pine, and provide comfortable accommodation for 360 persons. The architect is Mr. J. Fawcett, of St. James' row, Sheffield; the clerk of the works is Mr. D. Brierly; the builder, Mr. J. Brierly, of Bolsterstone.

BOURNEMOUTH.—The Hahneman Convalescent Home was opened last week by the Lord Chancellor, who laid the foundation-stone of the building in the beginning of last year. The Home is situated on a plot of ground on West Cliffe, and is faced with Highbridge red bricks, and with terra-cotta arches and dressings. The walls to the rooms internally throughout have been dis-tempered with the Patent Silicate Co.'s washable grey distemper, the hall and staircase having a dado in Venetian red, with a stencil border of floral pattern. There is accommodation for 15 indoor patients; there is also good servants' accommodation; the health and comfort of the patients have been thoroughly considered in regard to sanitary and ventilation regulations, each room having been provided with fresh air (warm and cold) ingress, and also for the outlet of foul air, Banner's patent foul-air extractors being used to the extracting flues. The heating of the building has been properly considered and arranged. The work has been carried out satisfactorily by Mr. J. McWilliam, contractor, for £2,500, under the superintendence of the architect, Mr. C. C. Creeke, of Bournemouth.

CONFORD ST. MARY, WILTS.—This parish church has been restored from the designs of Mr. E. H. Lingen Barker, architect, of 7, St. Owen's-street, Hereford, and was reopened by the Bishop of the Diocese (Sarum) on the 11th inst. The original church consisted of nave and chancel, separated from each other by a pointed arch, springing from two circular columns with rudely ornamented capitals of Late Norman character. A south aisle, and west of the chancel, an eastern chapel were subsequently added. The present restoration has embraced new roofs, covered by tiles, the timbers within being open, and plastered between the rafters. The walls have been recoloured, the stone pavement of the passages and the chancel taken up and replaced with encaustic tiles, and new floors have been laid down. The woodwork of the tower is altogether new, the old and cumbrous west gallery has been removed, and the beautiful western window opened out. A large new window has been inserted in the south aisle, and the east window is also new. A new lancet-headed window has also been put into the south side of chancel, and a dark corner in the north-west of the nave has been relieved by a similar course. The handsome western porch has been rebuilt, and the church reseated throughout. A new warming apparatus has been laid down, and a new vestry of commodious proportions built. The churchyard has been levelled and surrounded by a substantial and handsome dwarf wall with new oaken gates, and the outside of the church is protected from the ravages of damp by a paving with channels to carry off the water. Mr. William Balcombe, of Kenilworth, Warwickshire, was the contractor, and the carving was done by Mr. Harry Hems, of Exeter.

ECCELES.—New cemetery chapels at Eccles, near Manchester, have been erected. The style adopted is Geometrical Gothic, of a simple substantial character. The chapels are widely varied in design, and in each a bell-turret forms a conspicuous feature. The material used is brick faced with Dmford Bridge parpoints, the dressings being of Runcorn stone. The walls are plastered inside, except in the coffin aisles. The woodwork generally is of pitch-pine, stained and varnished. The chancels, coffin-aisles, porches, and passages are laid with red and black Staffordshire tiles, and the windows throughout are glazed with quarries of various

tints, the heads being fitted in with geometrical patterns. The cost of the three chapels, lodge, and entrance gates is about £3,800. The builder, Mr. Napier, of Manchester, has carried out the work from the designs of Messrs. A. H. Davies Colley and J. W. Beaumont, the joint architects, to whom the first prize was awarded in open competition in 1877. The Roman Catholic chapel and burial ground were consecrated on Saturday last. The Church of England chapel, &c., were consecrated on Monday. The Non-conformist chapel will be opened to-morrow.

ELTHAM.—The parish church, which was rebuilt in 1874-75, by Mr. J. G. Naylar, of Rochester, from the designs of A. W. Blomfield, Esq., at a cost of upwards of £6,000, is, at last, to have the old adjacent wooden spire removed, and a new stone tower and spire, by the same architect and builder, substituted. The amount of the tender is £2,677, but through a scarcity of funds the committee are at present only entering into a contract for the erection of the lower part, at a cost of £1,500, although they strongly hope that before the lower part is finished sufficient funds will have come in to enable them to complete the whole. Mr. Naylar was also the successful competitor for the erection of the Congregational Church, Holy Trinity Church, National School buildings, and Parochial room, all of which have been erected here within the last ten or twelve years.

LLANSANNAN.—The parish church of this village, formerly one of the most unsightly buildings in the diocese of St. Asaph, both within and without, was reopened on Thursday, the 12th inst., after restoration effected at a cost of £1,100. The old window openings on north and south sides have been filled with two-light lancets with pierced circular heads, in place of circular-headed ones, and three-light windows are placed at the east end of the nave and aisle of which the building consists. New freestone copings are placed on the gables, and a bellcote built between the western ones. A new porch has been erected, of wood framing on a stone base. The roofs have been reslated, the old lath-and-plaster ceilings are replaced by coed ceilings of red deal battens, divided into panels by ribs. In place of iron columns the arcade is now formed by wooden posts, chamfered and moulded and set on stone bases. The old pews, gallery, and flooring have been removed, and the plaster stripped from the walls. Open seating for 144 persons is now provided, and a place left at the west end for the placing of chairs as required. The floor of the chancel has been raised. The passages are of tiles in pattern, supplied by Webb's Worcester Tiley Company. The woodwork of ceilings, posts, screens, seats, door, and porch have been stained and varnished. The alterations have been carried out from the designs of Mr. R. Lloyd Williams, architect, of Denbigh.

MANNINGHAM.—The new Wesleyan chapel of St. John, at Park View-road, Manningham, was opened on Wednesday week. The building in the Early English style, has been erected from the designs of Mr. C. O. Ellison, architect, Liverpool. The chapel has a wide nave, covered by the roof in one span, the length is 113ft. 6in., the transept is 52ft. wide, and the chancel is 24ft. deep and of similar length. Accommodation is found in the body of the place for 750 worshippers, and in the side galleries for 250. The pulpit, font, and reredos are composed of Caen stone, with shafts of Mexican onyx, Derbyshire cavern spar, and Derbyshire marble. Messrs. W. Ives and Son were the contractors. The chapel and approaches have cost about £8,000.

MARY TAVY.—The reopening of St. Mary Tavy parish church, after restoration, took place on Tuesday week, under the most favourable auspices. The restored church is of the Early Perpendicular style, and was probably erected at a time contemporaneous with several other in this part of Devon, viz., during the 14th or 15th century. The contractor was Mr. P. Blouey, of Buckland, and Mr. J. P. St. Aubyn was the architect. The entire cost will be about £1,300 or £1,400. The belfry has five bells, and the tenor bell has been recast by Messrs. Warner, of London. The flooring is of Somersetshire tiles, with the exception of the chancel, which is fitted with Maw's encaustic tiles. The seats will accommodate from 100 to 150 persons.

METROPOLITAN BOARD OF WORKS.—At this Board on Friday, a desultory discussion arose with reference to a report brought up by the

Works Committee concerning the placing of accessories around Cleopatra's needle. A large model of the obelisk was exhibited, with the additions suggested by Mr. Vulliamy, the Board's superintending architect, in association with the engineer. It is proposed, in order to obviate as far as possible the present seemingly insecure base of the monolith caused by the rounding off of the corners, to enfold semi-dragons' wings around each angle, connecting these by a waved ornament in copy of the official monogram of Thothmes III., in whose reign the obelisk was hewn. The granite pedestals on either side of the obelisk is to be lowered and reduced in size and upon each is to be placed, facing the obelisk, a sphinx modelled from one in the possession of the Duke of Northumberland, which is of the period of Thothmes III. The sphinges and pterons, &c., are proposed to be of bronze. During the discussion some curious criticisms of the obelisk, its site, and the suggested accessories were offered; but eventually it was agreed to have plaster casts made, coloured to resemble bronze, for the temporarily garnishing of the Needle. Owing to the death of Mr. James McCleary, surveyor to the Board, the following promotions were made—Mr. James Bell, from second to first-class officer in the Engineer Department, at a salary of £200 a year, and Mr. John Pollard, from third to second-class, at £150 a year, Mr. J. McCleary, son of the deceased officer being appointed temporarily in the department at £100 a year. An offer was recently made the board by a Mr. F. Thompson, offering to erect a permanent glass roof over the greater portion of Leicester-square at his own sole cost, but it was decided to reply to him, stating that the board are not prepared to adopt the suggestion. The resignation of his seat, as representative of St. Luke's Vestry, was tendered by Mr. Joseph Storey, and was accepted. A letter was received from the Vestry of St. George-the-Martyr, Southwark, transmitting an extract from the report of their medical officer of health, stating that the houses in the several areas comprised in the artisans', &c., dwellings scheme in the parish are entirely unfit for human habitation in their present condition, and suggesting that the houses be immediately closed. It was referred to the works committee, as was also Sir H. A. Hunt's provisional award in relation to the Whitecross-street, St. Luke's, improvement scheme under the Artisans' Dwellings Act, 1875.

QUEENSTOWN CATHEDRAL.—St. Colman's R.C. Cathedral, for the diocese of Cloyne, erected on a hill-top overlooking Queenstown Harbour, was opened on Saturday. It has been in course of erection since 1868, from the designs of Messrs. Ashley and Pugin, of Dublin, and has thus far cost £80,000, but another £20,000 will be needed to complete the scheme. The style is 14th century Gothic, and the plan includes a tower, baptistery, nave, chancel with apse, north and south aisles, transepts, side chapels, and sacristies. The dimensions are: external—length, 210ft.; width across transepts, 121ft.; width across nave and aisles, 81ft.; internal—length, 190ft.; width across transepts, 106ft.; across nave and aisles, 70ft.; and with confessionals, 81ft.; and across nave, from centre to centre of columns, 37ft. A tower, 300ft., forms a part of the scheme not yet carried out. The west front is divided into three spacious entrances, and above will be a wheel window 25ft. diameter. The walls are faced with masonry, and the dressings, internal walling, wall shafts, and corbels are of Bath stone. The arcades are supported on columns of Cork red marble set on Sicilian marble bases, with limestone plinths, and having Portland stone capitals. The arcades between the side chapels and the chancel are supported by coupled columns of Cork red and Galway green marble alternately. The triforia are supported on shafts of red Aberdeen, surmounted by enriched canopies; from the level of the clerestory windows spring. The wall space is left to be hereafter filled with sinking and medallion, inlaying and jewelling with balls of green, red, and white marble. The prevailing carved ornament in the building is a shamrock, emblematical at once of Christianity and nationality. All the wall work, with the exception of the transept windows, has been completed, and also the six turrets, each 120ft. high, set on either side of the west gable and north and south transepts. The slates are on the ground ready to go on the roof over its present covering of

asphalte and the inner lining of oak. The interior furnishing is as yet of a temporary character, from the high altar to the seating for the congregation, and the grooming and carvings are also incomplete. The process of erection has been unusual. The foundations were laid by the building committee, under the immediate supervision of Mr. C. Guilfoyle Doran, clerk of works, and directly controlled by the architects. The contract for the superstructure was taken by Messrs. Meade and Son, of Dublin, but owing to a misunderstanding with the building committee the firm relinquished their contract in 1871. Since that time the committee have resumed the original method of working under Messrs. Ashley and Pugin and Mr. Doran, and they are still proceeding without interruption.

ROUPELL PARK, S.W.—The foundation-stone of a Wesleyan chapel in course of erection immediately opposite the Tulse-hill Railway Station was laid on Wednesday week. The church, which is designed in the Early English style, will be 136ft. long, and 55ft. wide, and will be constructed of Kentish ragstone, with moulded tracery and facings. The chancel will be of semi-circular design, 31ft. deep. The columns will be of polished Shap granite, with carved stone caps, the five arches forming the arcade being finely moulded, with similar bases. The walls will be of good thickness, and will be stuccoed. The seating will be of pitch-pine stained, and the area will accommodate 720 persons, the gallery holding 280. The roof will be of fine stained deal, wagon-headed; and in the basement will be six vestries, two classrooms, library, prayer-meeting-room, and infants' school. The large school-room, also in the basement, will be 51ft. by 50ft. The spire will rise to a height of 150ft. The architect is Mr. R. Bell, of 4, Union-court, Old Broad-street; and the builders are Messrs. J. and C. Bowyer, of Upper Norwood. The cost is £10,000.

SALISBURY.—The new Congregational Church in Fisherton, Salisbury, was opened for public worship on the 11th inst., when all the services were well attended. The church is built in the Early Decorated style, and consists of nave and aisles, with an apse, or recess, at the end, an organ-chamber and vestries, and tower and spire at the south-east angle, there being two entrances in the front and a side entrance to the vestries. The walls of the church are of concrete, faced externally with Swanage stone, in drop-coursed work, having for dressings, &c., Corsham Down stone, and internally with brickwork, which is finished with Portland cement stucco. The ceilings are of plaster, with the main timbers of the roof exposed to view, thus forming panels. The woodwork is of pitched pine stained and varnished, and the passages and centre of the apse have tiled floors laid to pattern. The large window in the apse is filled with stained glass by Mr. Drake, of Exeter, and was presented by Dr. Nathaniel Rogers, of that city. The arcades that divide by five bays the nave from the aisles stand upon octagonal bases, the columns are carried well up, and circular capitals support the arches themselves. The arch of the recess is a fine piece of masonry, carried on carved capitals, under which are columns and ornamental corbels. The organ stands upon a dwarf Bath stone panelled and carved screen; and the end of the recess beneath the stained glass window is divided into four triple-headed bays, supported by double red Mansfield columns with carved capitals. The spandrels between and over these arches are filled with diapered work, interspersed with paterae in large circles. The front of the church consists of the gable end of the nave pierced with a large five-light window, with geometrical tracery in the head, having attached columns on jambs, with carved capitals and moulded bases. Under this window extends sunk panelling in Bath stone. Lower still are three single-light windows. On the left is one of the entrances, and on the right is the tower and spire, and connected with the nave by a vestibule in the tower is the second front entrance. Both the entrances have a gabled and moulded arch filled in with sunk panelling over the doorways, these being supported by detached columns with carved caps and moulded bases. The total internal length of the building is 105ft. 6in.; the width, 49ft. 6in. The height of the nave is 50ft., and the height of the aisles 20ft. The arched of the clerestories is carried on Portland stone columns, with moulded capitals and bases. The tower

and spire rise to a total height of 132ft. to the top of the vane; the tower is built in three stages, the lower being one of the entrances to the chapel, the next being a chamber for ringers or store-room; and the third for bells, a circular staircase at the side of the tower giving access to the upper stages. The designs were furnished by Messrs. Tarring and Wilkinson, of London, and the work has been carried out in a most praiseworthy manner by Mrs. Hale and Son, of Salisbury, the carving being executed by Mr. Harry Hems, of Exeter.

OWERBY.—The church at Sowerby was reopened on Wednesday week after restoration. It was built in 1762, and is in the Italian style, having a nave separated from aisles by an arcade of the Corinthian order, and galleried round, and an eastern apse. The roof to the nave having been found to be unsound, it has been completely repaired, and the plastered ceiling replaced, two large sunlights being inserted into it. A partition which separated the western bay into an ante-chapel has been swept away, the organ has been placed at the east end of the north aisle, and a vestry formed in a corresponding position on the south side. All the pews in the area of the church have been taken down, and the wood converted into open benches; the passages have been laid with tiles, and Tobin's ventilators and Lumley's heating apparatus have been placed in the church. By placing a screen on either side the eastern bay of nave, a quasi-chancel, 20ft. in depth, has been formed. The side screens are Italian in design, and are formed in Caen stone, the shafts being in various coloured marbles, and the capitals boldly carved. The dwarf screen separating nave and chancel is of red granite and serpentine, with the panels filled in with rare marbles. The floor of the chancel throughout is laid in mosaic tilework; the steps and altar foot pace are of white marble. The holy table and choir stalls are of oak. A new pulpit will soon replace the large three-decker. Three windows have been filled with stained glass, by Messrs. Heaton, Butler, and Bayne, of London; the subjects are "The Charge to St. Peter," "The Baptism of Our Lord," and "The Charity of Doreas." The works have cost £3,000, and have been carried out from the designs of Messrs. Middleton and Son, of Cheltenham. Mr. Crawshaw was the contractor for masonry, Messrs. Haigh for joinery, and Messrs. Baneroff, of Halifax, for plastering. The brass lectern was made by Mr. Letheran, of Cheltenham, and the mosaic floor has been executed by Messrs. Powell and Son, of London.

TONBRIDGE.—The parish church was reopened on Wednesday week, after complete restoration, from the designs of Mr. Ewan Christian, carried out at a cost of £14,000. The stucco has been removed from the external walls, which have been repaired and re-pointed. The unsightly iron bands have been removed from the tower, which is considered perfectly safe without them. In the interior, the galleries have been removed, the walls uniformly stuccoed, the high-backed pews replaced by open seats in teak, and the nave roof entirely renewed in open timber construction. The south aisle has been rebuilt and re-roofed, and an additional aisle added, extending as far as the chancel, so as to form an organ-chamber and vestry. The new pulpit, of oak and teak, well carved and supported by a carved stone pedestal is a special gift. The new font is of Hopton Wood stone, and stands on a white stone base surrounded by Devonshire marble columns. The lighting is by gas coronae, and the heating by hot-water apparatus. The passages have been paved with encaustic tiles. A small stained-glass window has been placed in the chancel. In the tower is a new clock, made by Messrs. Moore and Sons, of Clerkenwell. Messrs. Punnett and Sons, of Tonbridge, were the contractors, except for the reseating, which was carried out by Messrs. Cornish and Gaymer, of North Walsham, Norfolk.

TRURO CATHEDRAL.—At a meeting of the executive committee of the Truro Cathedral Fund, held last week, Mr. Pearson submitted his plans for the new cathedral, and it was agreed to recommend them to the General Diocesan Committee, with a suggestion that the first part, consisting of the choir and its aisles, should be commenced immediately, at a cost not exceeding £35,000. The plans display the chief points of a structure in the 13th Century style of architecture, and include a central and two western towers. The ground plan shows the proposed

ultimate erection of a cathedral proper, with nave, aisles, transepts, and choir, together with cloisters and cloister court. The space under the choir will be used for vestries, temporary chapter-room, &c. It is proposed that the aisle of the present church should be worked into the building, and the south porch of the transept is made perceptibly richer in order to blend with the more profuse ornamentation of the south aisle wall. At the west end of the old aisle there is a tower, in which it is proposed to place the present peal of bells, and on it will be a clock. This tower and the old aisle (which is to have an altar at the east end) will form the old parish church of St. Mary, but the tower will be the only one till one of the great cathedral towers is built. This, however, will not be included in the first part of the work, which will be confined to the east end of the building. The cost of the nave and transepts is estimated at £60,000, in addition to the portion of the scheme now in contemplation.

CHIPS.

The Wakefield Town Council have directed Mr. Colcutt, the architect of the new town hall, now approaching completion, to provide four faces to the clock in the tower, and to procure tenders for the same. At the same meeting tenders for fittings and fixing pipes in the town-hall were considered, and that of Mr. Wm. Holdsworth, the general contractor for the works, was accepted. Three bells for the tower, one for striking the hour and two for use in case of fire, were ordered of Messrs. Taylor, of Loughborough. At the same meeting some grumbling arose as to the fittings of the town hall, which were alleged to be very expensive, about £14,000, and the total cost was said to be far in advance of the original estimates.

Mr. Joseph Cooper, F.S.A., of Kingston, near Lewes, died on Sunday week, aged 46 years. As an ardent archaeologist, Mr. Cooper devoted great energy to the Sussex Archaeological Society, and his contributions to their "Collections" have been numerous and valuable. Unfortunately, his papers relating to antiquarian researches in the neighbourhood of Lewes, Swanborough, and Kingston have been left unfinished.

The members of St. Paul's Ecclesiological Society will visit the chapel of Lambeth Palace on Saturday afternoon (to-morrow) under the conduct of Mr. John P. Seddon. Members are to meet at 4 p.m. in the first courtyard of the palace.

The Iron and Steel Institute have accepted an invitation from the Mayor of Liverpool to visit that town; they will probably hold their meetings there on September 24th, 25th, and 26th.

The project of erecting a monumental statue to John Knox in Edinburgh has been revived, and a committee has been formed to carry out the intention.

All Saints' Church, Eastbourne, was consecrated on Wednesday week. It consists of a nave, side aisles, and chancel, and is built of Kentish rag with Bath stone dressings. At a future day a tower and north and south aisles to chancel are to be added. The seats are of pine and the pulpit is of dark oak and ebony. The architect is Mr. Streatfield, of Marlborough-street, London, W., and the contractors are Messrs. Carruthers, of Reigate. The outlay has been about £11,000.

Mr. Thomas Oliver, architect, of the firm of Messrs. Oliver and Leeson, has received instructions from the Newcastle School Board to report upon and prepare designs for enlarging the extensive Board schools at Westmerland-road, in that town.

A new vicarage is being erected for the parish of Locking, Somerset. The architect is Mr. A. Whitehead, of Clevedon; and the contractors are Messrs. Perry and Harvey, of Weston-super-Mare.

The extensive premises erected some few years since by the Worle Brewery Company, Somerset, have recently been purchased by the Weston-super-Mare Sanitary Steam Laundry Company (Limited), who are now making the necessary alterations and additions for carrying on their business on these premises. The works are being executed, under the superintendence of Messrs. Price and Wooller, by Messrs. Perry and Harvey, of Weston-super-Mare.

Mr. John Pinches, of 27, Oxendon-street, S.W., has sent us one of the medals executed and struck by himself, from the design of Mr. J. P. Seddon, to be given as prizes at the Westminster Industrial Exhibition. The design of the medal is sensible and good, and the execution all that could be desired.

The parish church of Oakwood, near Dorking, is undergoing restoration and enlargement. Messrs. Colls and Sons, of London, Camberwell, and Dorking, are the contractors.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the **ENGLISH MECHANIC AND WORLD OF SCIENCE**, most of them from the pens of the leading scientific and technical authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Two-pence, of all booksellers and news-vendors. Post free 2d. Office: 31, Tavistock street, Covent-garden W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33f. 30c.). To India (via Southampton), £1 6s. 6d. To all of the Australian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O. and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—C. A. H.—B. B. Co.—J. C. and Co.—W. McF. and Co.—T. E.—C. and G.—J. D. Y. and Co.—S. F. C.—B. B.

APPEAL.—(We cannot advise on the very insufficient data forwarded. What you call "whims and ideas" may be important matters in the architect's estimation. If you have a written contract your position is probably defined therein.)—J. J. C. (Only section and sketch are required. Sheet to be 14in. by 22in.)

Correspondence.

THE SO-CALLED STOUP AT LEWANICK.

To the Editor of the BUILDING NEWS.

SIR,—This is a very curious object, and one would like to have more information about it, and especially as to its exact position in the church. Will Mr. Hens give us a sketch plan? It is not a stoup, but a cross-stone—a very rare thing to find in a parish church. From the woodcut, I doubt whether the base and the top belong to one another.—I am, &c.,

J. T. MICKLETHWAITE.

GLOUCESTER ASYLUM COMPETITION.

SIR,—We have here a new phase of the evils of competition, viz., the apparent coincidence of interests of the architect and the doctor; at any rate, the remarkable way in which the medical man writes up one design is, to say the least, highly objectionable. If you can do anything to stop this very dishonourable mode of proceeding, you will help the profession generally.—I am, &c.,

SUB ROSA.

SIR,—The letter of your correspondent of last week is very unfair and untruthful.

I can assure him the Visiting Committee do not know the plan he mentions.

No plans were prepared before the competition by the County Surveyor on the magistrates' instructions.

The County Surveyor is not a salaried officer; he merely receives a small retaining fee of five guineas for attending Quarter Sessions.

The whole of the preliminary plans and details for the preparation of the instructions to architects were prepared by the salaried officer, the Clerk of County Works, whose name your correspondent will see on the plan of estate supplied to competitors, and his appointment debars him from competitions of this kind.—I am, &c.,

FAIR PLAY.

NEW WESLEYAN COLLEGE, BIRMINGHAM.

SIR,—I congratulate the successful candidates in this competition on their beautiful designs, and the committee for so loyally following the advice of their referee, but it appears to me there is one paragraph in Mr. Waterhouse's report which is manifestly unjust to the remaining competitors, and calculated altogether to mislead the committee. The report says:—"In making these awards, I have compared and weighed the 42 designs—first, by the scales of the conditions, ascertaining their general adherence to these conditions, and especially to that of cost."

£23,000 is the sum named in the conditions which is to cover the total cost of college, out-buildings, boundary walls, &c. Now, does Mr. Waterhouse mean to tell us that the design placed first, "Ut Migraturus Habita," can be carried out for anything like that amount? Let not the committee lay that flattering unction to their souls. Having gone carefully into the question, I should call it a very cheap building at £30,000, and I question if any builder of substance could be found to undertake the works at that figure.

The large central tower, about 20ft. square and 70ft. high, is no doubt a beautiful feature in itself, but it serves no practical purpose, and every penny spent upon it will be in excess of the stipulated sum. There is a great waste of space, too, in the corridors, if the instructions are to be fairly interpreted. I think the design very handsome, and the plan one of the best in the room; but, with the greatest respect for Mr. Waterhouse's eminence, I venture to assert that his report, so far as the question of cost is concerned, is not only illogical, but unjust.

£23,000 is barely sufficient, with the most rigid economy, for the buildings required by the conditions, and it is somewhat disheartening to those competitors who have endeavoured to keep within the limit to find their labours thrown away in favour of a design which, however beautiful, practically ignores the important element of cost altogether; and I would submit that some explanation on this point is due from Mr. Waterhouse. I inclose my card, and am, &c.,

CANDEUR.

CHIPS.

A meeting of the creditors of William Brown Spencelayh, iron founder and Government contractor, carrying on business at Chatham and Rochester, has, according to the *Echo*, been held this week at Rochester. The liabilities are estimated at £20,000. It was agreed to accept a composition of 4s. 6d. in the pound, payable in six months.

Excavations are being conducted at the Roman Cemetery, Scaford, by Mr. F. G. Hilton Price, F.G.S., and Mr. J. E. Price, F.S.A., and have yielded several urns of Upchurch ware, containing burnt bones, &c., specimens of Samian and Dunrobrivian pottery, flint cells, flakes and scrapers, and also a Roman coin of either Faustina or Antonia.

An inquiry was held at Margate on Thursday last week, before Mr. Arnold Taylor, C.E., an inspector of the Local Government Board, with reference to an application from the Margate local board for sanction to the purchase of the undertaking of the Margate and Broadstairs Waterworks Company, and for sanction to borrow £60,000 for such purpose, and £7,000 for works of street improvement. The rate of purchase for the Water Company was stated to slightly exceed 23 years' profits. In the course of the inquiry as to street improvements, the inspector stated that if the Town Council obtained a loan to execute certain works in a certain material they could, if they so desired, carry it out in a better and more durable material and defray the extra cost out of current rates.

The last vestige of Temple Bar—the piers on the southern side of the Strand and Fleet-street—were cleared away by the contractors on Friday night and placed with the other numbered stones on the vacant ground in Farringdon-street. The erection of the street front of Messrs. Child's new banking premises, from the designs of Mr. John Gibson, is being rapidly pushed forward.

At Silksworth, near Sunderland, a new Wesleyan chapel has just been opened. It seats 500 persons and has cost £1,300.

Intercommunication.

QUESTIONS.

[5805.]—**Eddystone Lighthouse.**—I shall feel obliged if any of your correspondents will inform me the cost of the lighthouses built on the Eddystone rock by Winstanley, Rudeyard, and Smeaton respectively.—Thos. PROCTOR.

[5806.]—**Builders' Day Account.**—I have lately finished a large contract, under a London architect in the provinces, and before this contract was complete orders were given me by the building committee, not under the supervision of the architect, for sundry internal fittings, chiefly joiner's work, also alterations to plumber's work, &c. These works have been kept in my books as "Labour and material." No doubt the committee had an eye to "Architects' commissions," as I was requested to give rough sketches to them of the works before commencing, but no question as to cost. I was asked for my account, which they now have, a weekly statement of all the work as clearly given as it is possible to make out one of these accounts. Of course, when they received the same it was greatly in excess of what they intended to spend, and was an exorbitant charge. I now hear it has passed into the hands of one of their "Local Architects." The question with me is "what does he know about it?" Cannot I stand in the same position as a grocer or draper—i.e., say, "That is my charge; if you had wanted anything cheaper you should have gone to another shop? I have done a good job and do not intend to take less unless I am legally obliged to accept what you or anyone else thinks is a fair price." No doubt he will want to make it less, to let the building committee see he is of some service to them. Am I safe in saying "I shall not take less: that is my account, and I shall not alter it"? A reply from one who has been in the same fix will oblige.—X. Y. Z.

[5807.]—**Party Walls.**—I would feel much obliged by some kind reader letting me know the following:—I have, suppose, a small house of two stories, and my neighbour's house is three stories high. He wants to re-erect his house, and the wall between has to be rebuilt in consequence. I must add that the wall seems to have been originally built on his ground, and that I have no dues going into it. What proportion of the cost shall I be liable for?—ENOTHEKA.

[5808.]—**Wydraft.**—Can any reader inform me of meaning of this term in legal documents?—J. R. B.

REPLIES.

[5773.]—**Lime.**—It would be very interesting to know where J. S. Goldthorp has learnt that "poor or meagre lime" is the term generally used for hydraulic lime. I quote what Mr. George R. Bunell says in his treatise on "Limes," &c. (Weale's series), and who states that he had consulted and often literally copied from the numerous works. "The limestones containing insoluble silica in the state of sand, magnesia, the oxides of iron and of manganese, in various respective proportions, but limited to between 15 and 30 per cent. of the whole mass yield poor limes," and in another place he says that "the poor limes are those which either do not augment in bulk at all, or only do to a very trifling extent when slaked. They do not harden under water more than the rich limes, and are acted upon by that agent in the same manner, excepting that they leave a small residuum without consistence." And again, respecting eminently hydraulic limes, he says:—"Their change in bulk is invariably as small as that of the poor limes. It is to be observed that all the qualities of lime, whether rich, poor, or hydraulic in any degree, assume indifferently any colour. They may be either white, grey, yellow, buff, or red, without any corresponding change in their quality, as far, at least, as our present knowledge of the art of lime-burning will allow us to assert with any degree of certainty." With respect to rich limes, he says:—"The rich limes are the purest metallic oxides of calcium we possess, and the purest the carbonate of lime from which they are obtained the more distinctly marked are the appearances from which they derive their name. These are that they augment in volume to twice their usual bulk, or even more than that when slaked in the usual manner. If employed by themselves without any admixture of substances, their consistency, even after many years of immersion, is the same as on the first day. If exposed to pure water frequently renewed, the very last particle would be taken up in solution by the water." Then with respect to the arbitrary terms rich or fat as the reverse of poor, I shall quote the translation given in the *Civil Engineer and Architects' Journal* of General Treussart's definitions. "For a long time those limes which had the property of hardening in water were called meagre limes, and those which had not this property were called fat limes. These denominations were given because the first increased but little in bulk when made into paste, while the other gave considerable augmentation of volume, and because fat limes formed with the same quantity of sand a much fatter and more unctuous mortar than meagre lime." And he goes on to say "but the denomination meagre lime is altogether improper to indicate limes which enjoy the property of hardening under water, because there are limes which augment their volume very little on being made into paste, and at the same time possess no hydraulic property," and when "J. S." shall have read this I think he will see that he was mistaken, but if he should not so consider, I do not think that anything would convince him of a mistake on his part.—HENRY AMBROSE.

[5775.]—**Heating Kilm.**—The apparatus referred to by me was fixed by Heurne and Co., Liverpool, and "H. D. H." will be able, I have no doubt, to get the cost from them. The one I saw would suit "H. D. H." well, and would be just the thing for the purpose he names. The pipes are on the floor, and the heat would rise through the racks and frames and throughout the room. The heat, 110°, would be easily obtained and maintained. I cannot say cost of fuel per day, but there is a saving, I am told, as compared with steam, &c. Care should be taken in fixing room to see the heat does not escape. All walls should be well covered.—J. A. BUCK.

[5787.]—**Strains on Collar Beam Roofs.**—Henry Ambrose is thanked for his reply. To treat the weights, however, acting on the rafter as concentrated at the plate and apex, when in the case put it would really be distri-

luted along the rafter, seems unlikely to give a true result. Would it not be better to consider the weight on rafter as acting through its centre or centres of gravity? The method proposed shows a tensile strain only on the collar, and no doubt that is true when the collar is so low on the rafters as practically to connect their feet; but when the collar is placed higher on the rafter there is certainly another force brought into action upon it—namely, that of thrust, for it then becomes a strut between the rafters and tends to prevent them from bending under their load. I am inclined to think that to get the nearest approximation to the truth, the best method would be to consider that the weight borne by so much of the rafter as is above the collar is held in equilibrium by the collar, and then to consider that upper triangle of the roof as a weight to be supported by two inclined struts—i.e., the lower parts of the rafters abutting on the wall-plates. The strains on the upper parts of rafters and on the collar itself could be determined separately: the result would give a tensile strain on the collar. In the second part of the investigation the weight of the upper triangle of roof acting on the upper ends of the inclined struts would develop a thrust along the collar, equal and opposite to the thrust tending to separate the walls. The difference between this thrust along the collar and the tension exerted along the same member by the weight above the collar would seem to give the true strain upon it—at least, that is my present view of it. I shall be glad if "H. A." or any other correspondent will help to further elucidate this problem.—S.

[5794].—**Timber.**—Laslett's "Timber and Timber Trees" is a good work on the subject. I do not know the publisher's name.—G. H. G.

[5801].—**Cellar.**—Apply asphalt to the bottom and, say, 2ft. 6in. up the sides. Claridge's asphalt is considered the best for such a purpose.—SHEEVE.

[5803].—**Proportion in Church Architecture.**—R. W. Billing's work on "Geometric Proportions" is one of the best treatises. See also Chantrell's paper on the "Geometric System" in the *Transactions of the R.I.B.A.* "Perplexed Student" would find the subject treated of in Gwilt's "Encyclopedia." The proportion of nave is different in many instances; a good proportion is 3 to 3½ times the width. With respect to the height, a proportion of 3 squares to the plate is pleasing, the square being measured upon the distance between the centres of two piers. The best method is to divide the plate into squares or circles, and to proportion the lengths and heights upon these. The equilateral triangle was often used in proportioning the plans and sections of our churches, though some architects have no other rule than their own fancy, or some "rule of thumb."—G. H. G.

STATUES, MEMORIALS, &c.

KILMARNOCK.—Mr. W. G. Stevenson, Edinburgh, has just completed, in Silician marble, the statue of Burns, intended to form the central feature of the Kilmarnock monument. The figure is poised on the right leg, the left being slightly advanced. The left hand grasps a note-book, resting on a broken stump, near the root of which a daisy nestles; and the right holds a pencil. In the head, as well as the costume, the well-known Nasmyth portrait has been closely followed. Standing, with its base about 9ft. high, the statue is to be placed on a pedestal, 4ft. in height, within a sort of shrine, having an open pointed arch in front and at either side, through which a full view of the figure will be obtained. This structure forms part of a building in reddish freestone, rising from a terrace approached by flights of steps on an elevated part of the Kay Park. Its interior will be appropriated partly as a keeper's house, partly as a museum for the reception of Burns' relics. The whole cost of the work is, we understand, about £3,000, of which £800 is the price of the statue.

WATER SUPPLY AND SANITARY MATTERS.

NAFFERTON.—A discussion occurred at the last meeting of the Duffield rural sanitary authority with reference to the construction of drainage works at Nafferton. The work was completed about twelve months since, at a cost of £1,200, Messrs. Clark and Pickwell, of Hull, being the engineers, and Mr. B. Roberts, of Lowmoor, Bradford, the contractor. A few weeks ago one of the principal ratepayers wrote to the Local Government Board, complaining that the scheme was almost a total failure. At the meeting of the authorities a letter from the engineers was read, stating that they had examined the works and found that in nearly every case the work was faulty in construction. They laid the entire blame on the clerk of works, who was appointed by the authority, and recommended that a long length of the main drain should be taken up and relaid. This they would do for £10, provided they were allowed to send their own men to do it. The offer was accepted.

THE SEWERING OF ST. ANNE'S-ON-THE-SEA.—A meeting of ratepayers of St. Anne's-on-the-Sea was held on Saturday week, for the purpose of considering a scheme for sewerage of the district, which had been prepared by Messrs. Maxwell and Tuke, architects, of Bury, Lancashire. Mr. Maxwell, the architect of the town, referred to the present unsatisfactory drainage, to the difficulties caused by the flat site of the town, and to the danger of fouling the shore and so preventing bathing. He explained that he should recommend the adoption of

Isaac Shone's pneumatic system, and that the town should be divided into seven sections, in each of which the sewage would be conveyed to a centre and lifted by Shone's ejector into an hermetically sealed pipe, and forced along that pipe to any place suggested by the authorities. By this division of the district the sewers need only be 7ft. or 8ft. deep, instead of from 17ft. to 18ft. He estimated the cost at £2,500. After some discussion, and the hearing of statements by Mr. Isaac Shone, the inventor of the pneumatic system, a committee was formed to make inquiries into its working, and to report thereon.

THE FLOODS IN SOUTH-EAST NORFOLK.—Sir John Hawkshaw, C.E., has examined the flooded districts about Yarmouth and Lowestoft, lying adjacent to the Yare, the Bure, and the Waveney, and has presented a preliminary report embodying the remedies which suggest themselves to him. The district drained by the three rivers which discharge their waters by one common outlet into Yarmouth Harbour has an area of about 1,200 square miles. The lowlands in the district with which the report deals occupy an area of about 68,000 acres. The greater part of these lands lie along the tidal parts of the rivers, but considerable tracts above the tidal districts are also liable to be flooded. The tide flows up the Yare 29 miles, the Waveney 27 miles, and the Bure 25 miles. The surface fall of the rivers is only about 2in. per mile. The report states that if floods are to be prevented the river channels must be enlarged and additional sluices and weirs provided. An obvious improvement, the report continues, might at once be effected and at no great cost, by discharging a part of the flood-waters of the Waveney into the sea through Lake Lothing, at Lowestoft.

THE DRAINAGE OF SOMERTON.—At the Bristol Assizes in February, Mrs. Rachel Bissett, widow, sued the Guardians of the Langport Union for £415, balance of account alleged to be due to her, on a contract for the drainage of Somerton entered into and partly executed by her husband, and finished by herself as executrix, with the consent of the guardians, who were acting as the sanitary authority of the parish of Somerton. The defendants denied that anything was due, and pleaded that the contract under which the work was alleged to have been done was not complied with; they also set up a counter claim, by which they said the work was not done in a workmanlike manner, and within the specified time. By consent of both parties to the suit, a verdict was founded for the plaintiff on her claim, and for the defendants on their counter-claim, subject to a reference to Mr. A. J. Mackay, barrister, as arbitrator, who has now made his award. He directs the verdict entered for the plaintiff to be set aside, and instead thereof a verdict entered for the defendants, the verdict entered for the defendants on their counter claim to stand. He adjudges that the defendants have sustained damages in respect to the matters alleged against the plaintiff in the counter-claim to the amount of £103 4s. 10d., and orders the plaintiff to pay that sum, and all costs of the action and of reference.

LEGAL INTELLIGENCE.

AN ARCHITECT'S CHARGES.—"No Defence?—ABUSE PLAINTIFF."—At the Ashton county-court, on Thursday, an action was heard, John Joseph Butcher against Thomas Jones.—In August, 1877, defendant (a retired grocer) purchased a plot of land on the Dukinfield estate, at the Lakes, and applied to plaintiff, an architect in the town, to prepare plans for building two houses, the cost of which was not to exceed £600. Plans were drawn, and approved by the local authorities, the charge for which was 1½ per cent. on the £600. Afterwards defendant requested him to make out quantities, and this was done at a charge of 2½ per cent. Then defendant decided to have five houses built on the land instead of two, these five to be cellared, and the charge for the altered plans to be £2 per house. The plaintiff was requested to write letters to contractors instead of advertising for tenders, for which a charge of 10s. was made. In all plaintiff claimed £33. He had received 30s. on account, but the plans and specifications had been made no use of, and defendant refused to make payment; he alleged losses by limited liability companies, and had told plaintiff to get it the best way he could.—Mr. J. S. Eaton, architect, Ashton, deposed that the charges were fair and reasonable. For the defence, defendant's solicitor characterised this action as a gross attempt, by a manufactured account, to extort money from plaintiff. The latter had forced himself upon defendant (to whom he was then a stranger), and said he had heard that defendant had purchased some land for building purposes, and begged to be allowed to draw the plans. Defendant said he wanted the houses similar to two in Downsap-lane, which they went to inspect. Plaintiff agreed to draw the plans for 30s., which he had been paid. Whatever else complainant did

as to making out specifications, &c., was entirely without authority, and the statement as to other arrangements were untrue.—Defendant himself was put in the box, and positively swore to what his advocate had stated. He did not consider he owed plaintiff anything. He had given up the land in December last, and had never been asked for payment till quite recently.—Plaintiff's counsel said defendant ought to be sent to Salford sessions to be tried for perjury.—His Honour said it was really an undefended action, and gave judgment for plaintiff, with costs.

QUANTITIES.—Tomlinson v. Adamson and Sons.—This case, tried at the Brentford County Court, on Thursday, May 29th, before Mr. Serjeant Wheeler, was a claim for £14 5s., being 2½ per cent. for working out quantities relative to certain buildings to be erected for a Mr. Charles Bonn, and which the defendant tendered to build, and in which tender the plaintiff's claim was included as usual in all tenders, and which claim according to the custom of the profession should have been paid to the defendant on the first instalment paid by Mr. Bonn to the defendant; but defendant had not paid plaintiff, although Mr. Bonn had paid defendant over and above the contract price. His Honour, after hearing the evidence and arguments of the legal gentlemen engaged, came to the conclusion that beyond a doubt plaintiff had done the work and ought to be paid, but as there was no priority of contract between the plaintiff and defendant, Mr. Bonn, the client, must pay the plaintiff and recover that sum from the defendant, that is, if the amount in question was included in the tender by the defendant. His Honour allowed the plaintiff to withdraw from the case and receive back his hearing fee.

CHIPS.

The Heaton portion of the new Armstrong Park, at Newcastle-on-Tyne, was opened to the public on Wednesday week. The area of this section of the park is 23½ acres; it is 1½ miles from Newcastle town-hall, and is surrounded within 2,000 yards' radius by a population of 30,700. The whole of the works involved in laying out the park, which have cost nearly £2,000, are from the designs of Mr. A. M. Fowler, borough engineer, and the construction of roads, which has been done by day-work during the winter and spring, has been superintended by Mr. Fulton. The lodge has been let by contract to Mr. R. Hardbottle for £400, and is nearly completed.

In a convocation held at Oxford University on Tuesday week, it was unanimously resolved to accept with thanks an offer made by a Fellow of All Soul's College, to give the sum of £300 yearly for three years for the foundation of a travelling studentship for the prosecution of archaeological research, and a board was appointed to elect a student.

Mr. Kendal and Mr. Hare have, as is known, taken the St. James's Theatre, the interior of which has been entirely altered. When they inspected their property they discovered only one defect in it—the intelligent architect had forgotten the staircase. This seems to be a habit with architects. The same mistake was made in Montague House, the town residence of the Duke of Buccleuch.—*Truth.*

A new Wesleyan chapel at Whingate, Armley, was opened last week. The chapel has been built of brick, with a stone front, and will accommodate 400 people, at a cost of £3,200. The architect was Mr. John Simpson, of Cebourg-street, Leeds.

The Wigton Local Board considered and approved at their last meeting plans prepared by Mr. Hodgson, C.E., of Hexham, for the sewerage of the town and sewage purification. The scheme is designed on the separate system, and the outfall works are in a field at Long Tarn, two miles north of the town. The estimated cost is £5,000, to which must be added £430 for a small district above the town limits.

The parish church of Euxton, near Preston, an interesting structure built about 1513, was reopened on Wednesday week after restoration. New flooring has been laid throughout; the pews have been replaced by open benches; the chancel has been raised and roofed, and a new Communion-table placed within it. The outlay has been about £400.

A Local Government Board inquiry was held at Twickenham on Wednesday week, before Major Hector Tulloch, C.E., inspector, with reference to an application from the local board for sanction to borrow £5,000 for purposes of sewerage.

The Archbishop of York, last week, reopened, after complete restoration, the parish church of Menckton. Mr. J. Fowler, F.R.I.B.A., of Louth, was the architect, and Messrs. Keswick and Sons, York, the contractors.

The Cambridge Improvement Commissioners have accepted the tender of Mr. Ulwin for construction of sewers in Sturton-town.

Our Office Table.

THE eminent German historical painter, Johann von Schrandolph, died at Munich on the 31st of May. He was born in 1808, and was originally intended for the trade of a joiner; but, having taught himself the elements of drawing and painting, he obtained admission in 1825 into the Munich Academy of Arts, where he was instructed by Schlothauer in all the details of his art. He practised fresco-painting under Cornelius and subsequently assisted H. Hess in the frescoes at the Church of All Saints and the new Basilica of St. Boniface. He was one of the draughtsmen who composed the cartoons for the painted windows in the Auer Church, near Munich, and in the Cathedral of Ratisbon. In 1844 King Louis gave him the important commission to paint in fresco the Cathedral at Speier, and this occupied him for nine years. He also painted several altar-pieces in which deep and tender religious feeling is combined with great simplicity and nobility of conception and thoroughness of execution. His "Ascension of Christ" in the new Pinakothek in Munich, and his "Nativity of the Saviour" in the Maximilianeum are great works.

A NOVEL method of ventilation is ascribed to Dr. John Swinburne, of Albany, formerly Health Officer of the Port of New York, and has been applied to the Children's Hospital at Albany. The method consists simply in having large window-spaces, and filling nearly two-thirds of each with properly-arranged frames, on which is fastened ordinary, rather thin, unbleached muslin. The frames are so arranged as to slide, and when it is very cold three thicknesses of cotton cloth, two or three inches apart, can be brought into the window-space. The wards run east and west, and are fully exposed to the north, north-east, and east winds, and partially to the north-west. The rains beat on the cloth. One-third of each window is occupied by glass. It is said that the temperature in the wards is easily regulated, and that the quality of the air is always good.

On Saturday the President of the London Commissioners for the Sydney Exhibition attended at South Kensington Museum to pass the last of the pictures going out from England for the Fine Art Department of the Sydney Exhibition. A very valuable representative collection of 300 of the works of English artists has been secured, and such as it is quite safe to say was never seen before in any of the Australian colonies. Sir Frederick Leighton, Mr. Calderon, Mr. Elmore, Mr. Ansdell, Sir J. Gilbert, Mr. Prinsep, Mr. Watts, Mr. Poole, Mr. Alma Tadema, Mr. John Brett, Mr. Horsley, Mr. Armage, Mr. Sidney Cooper, Mr. Cooke, Mr. Storey, Mr. Cripp, Mr. Lehmann, Miss Montalba, Mr. Chevalier, and Mr. Haag are among the artists represented. Mr. Woolner, whose statue of Captain Cook already overlooks Sydney Harbour, has sent two or three pieces of sculpture. Mr. E. M. Barry, Mr. C. Barry, Mr. Wyatt, and Mr. Severn, contribute architectural drawings. The insurance value of the English pictures alone, calculated upon premiums paid by the Commission, exceeds £30,000; and there are 500 other pictures going from other countries of Europe. The miscellaneous collections include good collections of glass, china, porcelain, agricultural implements, and educational appliances and books.

THE decease of the well-known naturalist and archaeologist, Mr. Henry Noel Humphreys, occurred at the close of last week at his residence in Westbourne-square, Hyde Park, at an age not far short of 70. A son of the late Mr. James Humphreys, of Birmingham, he was born in the Midland metropolis in 1809 or the following year, and received his early education at King Edward's School, Birmingham. Among his most important works of an archaeological character between this date and 1856 may be specified "Illustrations of Froissart's Chronicles," "The Parables of Our Lord Illustrated," "The Coins of England," "Ancient Coins and Medals," "The Illuminated Books of the Mediæval Period," the "Coin Collector's Manual," the "Coinage of the British Empire," "Stories by an Archaeologist," and especially "The Art of Illumination," and "The History of the Art of Writing from the Hieroglyphic Period down to the Introduction of Alphabets."

A NEW ventilator called the "Empress," recently patented by Messrs. Ewart and Son, of the Euston-road, aims at a combination of two important principles. In the first place, by means of an Archimedean screw revolving within the tube a strong up-current is constantly produced, and secondly by the patented arrangement of the cone inside the wind fans, an additional up-current is insured and all possibility of downblow prevented. The obvious advantages of this combination are certainty of action at all times and an economy of weight and friction in the moving parts which is very desirable. One peculiarity which strongly recommends the new ventilator is that should it from any cause become fixed it does not become useless, but the principle of the fixed cone comes at once more powerfully into action, producing an up-current which the inventors state is equal in power to that of any known stationary ventilator yet introduced. The ventilator will be shown in action at the Kilburn Agricultural Show next week (Stand 36), and visitors interested in ventilation should make a point of inspecting it.

STAMFORD HOUSE, South Lambeth-road, a well-known old South London mansion, is, according to the *South London Press*, about to be demolished. Stamford House has, in addition to many fine old rooms, some interesting associations. Here Tradescant, the founder of the Ashmolean Museum, once lived, and next to the house was the famous Physic garden of the Tradescants, father and son both being eminent botanists and naturalists. The house has been purchased by Mr. F. Snelling, of Lansfield House, South Lambeth-road, for £2,650, and will be soon numbered with the past. Mr. Snelling is the iconoclast of South Lambeth, for this is the eighth old mansion he has bought and pulled down. This process is termed "improving" the locality. It may be so, but to one who in vain looks for the old spots he once knew and loved so well, and who now finds nought but staring bricks and mortar, painful to look at in their newness, the removal of these landmarks is a source of uneasiness.

WE stated some weeks back, in our notice of the new Art Union Buildings in the Strand, that the scagliola marble columns and pilasters had been placed in the hands of Messrs. Bellman and Ivey by Prof. E. M. Barry, R.A. They are now fixed, although not polished. The entrance-hall is enriched with Genoa-green and red Devonshire, and the first floor with Brocatella columns and pilasters. Mr. Barry has expressed himself as being much pleased with the work.

MESSRS. F. J. AND H. FRANCIS, the architects of the Grand Hotel, Charing Cross, have instructed Messrs. Bellman and Ivey to proceed with 22 scagliola marble columns for the grand salle; these will all surround iron columns, and will be fixed without showing joint.

THE annual meeting of the Royal Archaeological Institute will be held at Taunton in August next, from the 5th to the 12th inclusive. The official programme shows that on Tuesday, the 5th, the Mayor and Corporation of Taunton will receive the institute at an inaugural meeting, at which the President's address will be delivered, and afterwards the Institute will be the guests of the Corporation at a public luncheon. During the afternoon the visitors will go over Taunton Castle and the magnificent Late Church of St. Mary Magdalene, and afterwards inspect the various objects of interest in the town. The sectional meetings will commence at eight in the evening. On Wednesday there will be an excursion by rail to Cleve Abbey, of recent years made familiar to students by the painstaking researches of the late Edmund Sharpe and the Rev. MacKenzie Walcott, and from thence to Dunster Castle where a reception will take place, a conversation being given in the evening at Taunton Castle Hall by the Royal Archaeological Institute. On Thursday, the 7th, the annual meeting of the Institute will be held, and in the afternoon there will be excursions by carriage to Staple Fitzpaine and Castle Meroche. On Friday, the 8th, there will be an excursion to Bridgwater, Cannington, Stoke Courcy, and Fairfield, where a reception will be given by Sir A. A. Hood; afterwards a visit will be paid to St. Audries, thence home by rail. On Saturday, the 9th, there will be an excursion to Langport and Muchelney Abbey; having been received at Montacute House the members will visit Hambdon-hill, Stoke-sub-Hambdon Church,

Barrington Court, and Ilminster. On Monday, the 11th, an excursion will be made to Wells, where there will be a reception at the Palace, and to Glastonbury Abbey. Sectional meetings will be held in the evening, and on the following morning and evening. In the afternoon of Saturday there will be a closing excursion by carriage to Morton Fitzwarren, Bishop's Lydeard, Cothelstone, and Kingston. From this brief summary it will be seen that the district comprised in this year's excursion of the Institute is one rich in remains of monastic institutions, and containing several feudal castles, and some of the finest specimens extant of Perpendicular church architecture.

At Carpenters' Hall, London-wall, the porphyry columns, &c., in outer hall, and others of verde-antique, in the inner hall, with polished Parian capitals, are now being fixed. At a recent meeting the company and their architect (Mr. W. W. Pocock) approved of specimens for columns in the livery-hall, and Messrs. Bellman and Ivey have since received the order for same. They are in paonezzetta, with enriched Corinthian capitals, 19ft. 9in. high by 2ft. dia., and are made in one piece, without joint.

HAVING in view the domestic dangers to health arising from imperfect workmanship by plumbers and the use of improper so-called "sanitary appliances," the Council of the National Health Society have taken into consideration the most practical means of striking at the root of these serious evils. The conviction that a want of knowledge by working men of the elementary laws and application of the laws of sanitary science is a chief cause of these defects has led the committee to the conclusion that great good to the community would ensue from the practical teaching of elementary sanitary science to workmen actually engaged in building our houses. The Society proposes to organise a series of lectures and demonstrations to working plumbers. At the close of each series of lectures handsome money prizes would be awarded to those who gave the best evidence of having profited by the teaching. The National Health Society believe that not only would the lectures be very numerously attended, but that the matter will become one of general discussion in the workshops, and appeal to architects, builders, and the public generally for funds towards their proposed undertaking.

THE Home Secretary will be influentially supported on June 28th, when opening the Parkes Museum of Hygiene. Among others who will be present we may mention Viscount Cranbrook, Earl Fortescue, Sir Thos. Watson, Prof. Huxley, and the Mayors of Cambridge, Southampton, Salford, and Welshpool. The museum comprises an area of 3,500 square feet, independent of the library. This space will be quite filled by the day of opening, and the progress made during the past few weeks justify the assumption that the committee will succeed in making the museum a national institution of no mean importance. Communications may be addressed to the curator, Mr. Mark H. Judge, University College, London, W.C.

Glaser's Annalen contains a description of an improved method and apparatus for the manufacture of artificial sandstone. A thorough mixture of four to six parts of fine sand and one part of slaked lime is exposed for about three days to a high temperature and a pressure of more than three atmospheres, causing the formation of a silicate of lime which acts as a cement, so that the mass, when cooled down to the ordinary temperature, hardens. This hardening process continues for some weeks by exposure to the air, so that finally a product is obtained which is as hard and solid as good sandstone. The apparatus consists of a tank, into which the mixture is filled, and in which it is heated and stirred by a steam pipe, provided with a number of arms and rotated by belting or gearing. After the mixture has reached the proper temperature the steam is cut off, and a second vessel, inclosing the tank on all sides, is put into communication with the boiler. By this means the mass is heated for the period necessary. It is then run into a brick machine and shaped into the forms required. The process, it is claimed, effects great economy, especially for the manufacture of window-sills, &c. The apparatus used is made large enough to produce 250 cubic feet of material in every charge,—requiring, generally, three to four days.

Holloway's Pills are the sheet-anchor of the confirmed dyspeptic. A few trials will prove their potency in removing indigestion, biliousness, nausea, cructations, loss of appetite, want of sleep, and that utter weariness which always waits on a foul and disordered stomach. They act as alteratives, sedatives, and gentle aperients.—[Anvt.]

CHIPS.

The mission church of All Saints, in Blenheim-road, Ipswich, was reopened on Sunday week, after enlargement, from the designs of Mr. E. F. Bisschopp, of that town, the architect of the original structure. A western extension of 21ft., upon which is a bell-turret, affords 100 additional sittings, and a north transept 60 more, raising the accommodation to 370 seats. The additions correspond with the main structure, and are in red brick with handsand dressings of coloured brick and tile roofs. Mr. Coe, of Brooks-hall-road, Ipswich, was the contractor, and the total outlay for additions and new organ, built by Messrs. Godball, has been £515.

New schools are about to be erected for the Carlisle School Board in Denton-holme, from the designs of their architect, Mr. Birkett.

The annual excursion of the Kent Archaeological Society will take place on July 30th and 31st, and the meeting will be at New Romney.

The Exmouth Local Board, having applied to the Local Government Board for authority to borrow £1,200 for carrying out improvements within the district, a local inquiry was held on Thursday in last week before Col. Ponsonby Cox, C.E., one of the Board's inspectors. The surveyor, Mr. Packham, gave evidence showing that the money was required for asphaltting a path running parallel with the sea-wall and for street improvements spread over the greater part of the district.

At Penzance a Bible Christian chapel, erected at a cost of £2,000, has just been opened. It seats 500 persons, and there are a schoolroom at the rear and vestries beneath the main building.

Cwmbrwla Chapel, Swansea, was reopened on Sunday week after enlargement and the addition at the rear of a schoolroom and classroom. The architect is Mr. George Hauman, of Swansea, and the builder Mr. David Evans, of Brynhyfrydd, near Swansea. The outlay has been about £1,700.

Mr. J. Lawton Webster has been elected surveyor and inspector of buildings to the Malton local board.

The town council of Bradford received at their last meeting a report as to the falling in of about 120 yards of the main sewer in Shipley Valley in consequence of an insecure foundation, and ordered the same to be reconstructed at an estimated cost of £3,040.

On Wednesday week Mr. Arnold Taylor, C.E., held an inquiry on behalf of the Local Government Board at Heckmondwike respecting an application by the Local Board of Health for sanction to borrow £2,000 for providing a refuse destructor and for works and premises connected therewith.

Deep-water docks are to be constructed at Swansea, and the contract has been taken by Mr. T. Walker, of London, at £196,000. At the same port a new railway and other subsidiary works, estimated to cost £33,000, are about to be carried out.

The town council of Scarborough received at their last meeting, a report from the scavenging sub-committee who have visited Liverpool, Leeds, and other towns in order to obtain information as to the disposal of house refuse. They recommended the council to adopt the "destructor" as in use at Leeds for consuming part of the refuse and to convey the remainder out to sea. The report was referred back to the sub-committee with instructions to ascertain the probable cost of carrying out the systems recommended and of conveying out to sea the whole of the refuse.

The lock entrance to the Canal at Severn Quay, Gloucester, was reopened on Thursday, after having been closed for a fortnight to allow of the replacement of the lock-gates. The new ones are of green wood from South America and weigh 15 tons. They were constructed at the company's works at Saul, and were erected under the superintendence of Mr. F. J. Callis, assistant engineer to the company.

The consecration of St. Eidan's Church, Solva, in St. Bride's Bay, was performed on Wednesday week by the Bishop of St. David's. The church is a simple Gothic structure, seating 200 persons. All the fittings, including the seats, are of pitch-pine. The architect is Mr. Pearson, of London, and Messrs. Evans and John were the builders.

New buildings, erected at a cost of £3,500, for a mutual improvement society, were opened at Eastbourne on Thursday in last week by the Duke of Devonshire.

It is announced that the list of applications for shares in the Tramways Company of Germany, Limited, will close on Thursday next, the 26th instant.

A monument to the late Rev. John Roberts, the musician and divine, better known in the Principality as Ieuan Gwyllt, has been publicly unveiled at Caerthraw Cemetry, near Carnarvon. It is of polished Aberdeen granite, and is 16ft. high, and has been erected by contract by Mr. Hastings Sanfield, of Liverpool.

The first train over the new branch line of the London and North Western Railway from Dowlais to Merthyr was run on Monday week.

The Wakefield Corporation have fixed on a site for the proposed large new reservoir at the head of Ryburne Valley, within the parish of Halifax, and have arranged with the owners of property and the manufacturers, millers, and other owners of water rights. They have obtained sanction to borrow £300,000 for the works, to which some opposition is threatened in Halifax.

A stone-dressing apparatus, worked by an electrical machine, has just been invented by Mr. J. G. Cranston, engineer, of Newcastle-on-Tyne. He claims that the machine can be worked automatically or by hand, and that it performs the dressing of mill-stones or other masonry, and will drill rock with rapidity and accuracy.

The burial board of Cardigan, at their last meeting, adopted the plans of Mr. Alfred W. Szlumper, for the laying out of the new cemetery.

Mr. Evan Evans, of Troedyburn, has been appointed highway surveyor to the Llangollen district

In an action brought on Friday in Kingston-on-Thames county-court by a speculative builder against a tenant for a quarter's rent, Judge Lushington said such houses, as a rule, were a pollution to the country and a disgrace to civilisation, but as the defendant was a medical man, and had the premises carefully examined before he took them, there must be a verdict for the plaintiff, though he had no sympathy with him.

On Sunday week the nave of Tewkesbury Abbey was opened for service, having been temporarily fitted up to enable the committee to complete the restoration of the choir and the laying of paving.

The scheme for drainage of the rural sanitary authority of Croydon is now expected, says a local journal, to cost more than £20,000 over what was at first estimated, and the loan of £77,070 obtained. The accepted tender of Messrs. Cooke for the works is £78,228 18s.; a culvert for the river will cost £2,110 13s. 7d.; surveying and engineering, £4,930; and rights of easement, £500. The total cost, including £11,650 for purchase of land, will be about £100,000.

Mr. Johns has been elected district surveyor to the Crickhowell Highway Board, at £80 a year. There were twelve candidates.

At a meeting held at Charfield, Gloucestershire, on Wednesday week, the question was considered whether the existing parish church, at present in a very unsatisfactory state, should be restored and enlarged, or whether a new one should be built nearer the centre of the village, and it was decided to adopt the latter course.

A new Board school in Lothian-road, Edinburgh, is about to be erected. The building, which is to be three stories in height, is in the Domestic Gothic style, and is intended to accommodate 800 children. The cost, exclusive of site and furnishings, will be about £6,000. The designs are by Mr. Wilson, the architect to the Edinburgh School Board.

New Board Schools have just been erected at Ashford, East Kent, from the designs of Mr. Hanson, architect to the School Board. Mr. D. Fowler was the contractor.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Royal Institute of British Architects. Presentation of Royal gold medal and annual distribution of prizes. 8 p.m.
Aeronautical Society at Society of Arts rooms. Papers and experiments on "Flight." 8 p.m.

Trade News.

WAGES MOVEMENT.

BLACKBURN.—On Saturday the Committee of the operative stonemasons, now on strike, waited on the employers' committee and offered a compromise, undertaking to return to work if the masters will reduce wages 3d. per hour instead of 4d. The matter was brought before the employers at their meeting on Monday, and it was unanimously resolved to abide by the original proposition, to reduce the wages from 8½d. an hour to 8¼d. Late on Monday night the operative masons agreed to accept the masters' terms of 8½d. per hour, 49 hours per week. A further meeting has been since held, and there was a warm discussion, but a great many masons have returned to work.

THE BUILDING NEWS.

LONDON, FRIDAY, JUNE 27, 1879.

THE TURNER DRAWINGS AT THE NATIONAL GALLERY.

WE are glad to find that the authorities of the National Gallery have set apart two large rooms for the exhibition of the Turner drawings and sketches, which have been hitherto inaccessible to public view. An immense number are in the possession of the institution, and those now carefully exhibited in cases will in turn give place to others. Among the coloured sketches of Turner in his later style we may mention a series of views in France, Italy, and Switzerland of remarkable beauty and character. They generally retain their brilliancy of colour—here and there iridescent in hue, though we observe the exposure to light has in some instances been injurious to the pigments, a risk that will be avoided as much as possible by curtains which are made to draw over the easels and frames. As a series of views, few are more charming than the sketches labelled Houlleur, Amiens, Tancarville, Harfleur, Mantes, and Havre. In these a body colour has been used on a grey paper. In the view of Havre, a sketch which has excited the admiration of Ruskin, we find all the characteristic feeling of the great painter. "Between Mantes and Vernon" and "Amiens" are two charming sketches. In the latter (unfinished) the tint of brown is run upon the grey tone of the paper; the houses are roughly sketched in with sepia, while in the distance the cathedral and its spire are faintly discernible in blue. In this, as in others, there is a smudgy effect produced; the colours are mingled together when wet, but have that remarkable brilliant and opaline effect which only Turner could produce. "Jumièges" is a wonderfully characteristic sketch; the lighted abbey in the distance, relieved by the dark masses of shadow and colour, make a charming picture that is well known from its engraving. Many of the originals of the engraved series known as "The Rivers of France" are in the collection. Some of these sketches were made in one of Turner's annual tours, about the period 1825 to 1830. The sketches of Venice, on white paper, are still more glowing and brilliant examples of the great artist's power of light and shade and colour. In these his love of difficult atmospheric effects is marvellously displayed. Take his views of Venice as the "Guidecca looking out to Fusina," and "The Guidecca from the Lagoons." What a power of colour in the sky and water, they appear to blend in the glow of the horizon; the former has been copied literally in the painter's large oil-painting the "Approach to Venice." In the latter, the yellow, red, pink, and green are run together in that misty manner Turner loved to depict; we catch the impression of bright hues, but all detail is sunk in the general effect. In one of these drawings we observe the light fleecy touches of cloud, done in a metallic white pigment, has turned black. Exceedingly brilliant, as sketches, are those illustrative of Swiss scenery. The "Approach to the Splügen Pass" is an unfinished sketch, and, we believe, was the original of the work painted for Ruskin. It gives us a faint, though graphic, ideal of the pass connecting Switzerland with Italy. The receding Alps and the distant sunlit peak, with the tower on the foreground rock, are faithfully represented. Sketches from the

Lake of Zug, and "Venice, Sunset" are glowing bits of colour, the blue and yellow, and the streaks of crimson, and the deep blue distance truly luminous; the "Grand Canal, with the Church of Saluti," is a charmingly delicate sketch on white paper—the merest outline in colour, with the lights of domes left in the white paper. The artist has washed in all the effect with the least amount of colour, and, from a little distance, the sketch has all the completeness of a finished drawing. "Martigny and Chateau" is another rubbed-in effect of mountains and building, the chateau faintly outlined on the mountain side. The two sketches of the Righi from Lucerne are grand impressions, though in different keys; so is "Venice from Fusina," with its clouds of purple and carmine, touched or nibbed in upon a wet ground. We note some fine and very brilliant views of Lucerne, with its grand precipitous scenery, its buildings and castles; also a pair of sketches of Zurich, Coblenz, and Constance. The noblest characteristics of these spots have been focussed in colour, so to speak; it is true we have little detail; Turner leaves us the ideal beauty alone of these classical scenes; we get all the poetry that is possible to be got upon paper—in short they may be called painted poems. The Venetian and Alpine sketches are of recent date, and indicate the latest feeling of the painter, and those who remember the raptures of Ruskin will look at them with intense pleasure as the actual impressions of the scenery upon the artist's mind, and in this sense they possess even more value than the oil copies made from them. Many of these radiant sketches have not taken more than a few minutes; they are vivid impression in colour, indicated by a few touches of the brush, the local tints being put on while the paper was damp, while a few scrawls of the pen dipped in red, sepia, or violet give faint indications of masses of detail and groups of buildings or figures. Here and there we observe body colours applied, but the whole is harmonious and aerial. The handling indicates an impatient grasp of genius ready to generalise the first impressions of nature upon the retina while avoiding all detail; and the effect many of these sketches leaves upon us is that Turner was working in a vehicle not pliant enough for him to manifest the various modifications of light and shade and hue which caught his eye. It is necessary for the visitor to go prepared in the right temper of mind to appreciate what appear to many as unintelligent scrawls and smudges; but before he comes away he will begin to estimate at their true value the work of a man who regarded nature from the true poet's standpoint. His earlier sketches and drawings are no less worthy of study, however, and show that Turner commenced with the conventional idea of drawing. For instance we notice two sketches, one "The Hot Wells, Bristol," a highly-finished drawing; while another, "Folly Bridge, Bacon's Tower, Oxford," signed with the date 1787, shows a crudely drawn water-colour copied from a print, in which the outlines are drawn with the disagreeable distinctness observable in copies by novices. These drawings are particularly interesting as showing the change in the great painter's mode of delineation. Among the earlier works we may draw attention to a beautiful series of vignette designs for illustrations to Rogers's Poems, executed about 1830 to 1834. Some of these are gems of colouring, the detail and intensity of colour increasing to the centre of the picture. The "Ports of England," engraved in mezzotint by Lupton, about fifty years ago, are represented in a few original sketches. Of these, Scarborough, Stangate Creek, Whitby, Portsmouth, and Sheerness must be particularly mentioned as highly-finished water-colour miniatures, in which drawing, composition, and rich colour

are conspicuous. The series of sepia drawings for the Liber Studiorum, executed between the years 1807-1820, are to be seen also upon the walls, and exhibit Turner's early care for detail. Greenwich Hospital from the Hill, Rivaulx Abbey, Holy Island Cathedral, and Kirkstall Crypt are remarkable drawings exhibiting a wonderful power in architectural detail. Thus Holy Island Cathedral might be mistaken for the work of an architectural artist. The Norman pillars and arches are well drawn, and the perspective good. The tower of St. Mary's, Redcliffe, Bristol; York Cathedral, and the tower of Boston, Lincolnshire, are delicately-drawn pencil sketches, in which the outline has been largely filled in with detail—much of it executed with a freedom and feeling the architect would not despise. As a study of light and shade, Ruskin has pointed to a drawing in sepia of the remains of a Doric temple which now hangs over one of the doorways. Turner's earlier sketches of Rome show also a considerable knowledge of architectural detail, which in after years gave place to the broader and more genial branch of landscape in which he became so great a master. For masterly and complex composition, for balance and skilful grouping, in which a kind of ingenious intricacy appears, and especially for breadth and brilliancy of colouring, the studies of Turner at the National Gallery are well worth attention.

BRONZES AND IVORIES AT THE BURLINGTON FINE ARTS CLUB.

WITH some hesitation the committee of the Burlington Fine Arts Club decided to exhibit bronzes this year in their rooms in Saville-row. It would be flattery to say that the collection now brought together approaches in interest those of several former years. Still, no less than 550 articles, mostly of a high class, many of the very highest, have been contributed by members of the club and their friends. Neither in the bronzes nor in the ivories is there anything approaching to a complete historical series. What we really have is a collection of each of the description most fashionable at the present time, namely, Italian work of the 16th and 17th centuries. There are, however, a few Greek and Roman bronzes, chiefly those in Cabinet No. 1, belonging to the Rev. Montague Taylor, who is to be congratulated upon the possession of so many fine things, in number and quality only to be rivalled by the works exhibited by Mr. C. D. E. Fortnum in the same case and in several other parts of the room. No. 11, ornament of a vase, being a mask in bronze, inlaid with silver, the eyes formed of rubies, is a superb specimen of the choicest Græco-Roman work. From this precious fragment we can conceive what must have been the beauty of the complete work. It was found at Pompeii. Somewhat similar in shape, and probably for the same purpose is the handle of a vase (No. 7). This is evidently Roman of about the time of Trajan. The subject is said to represent the Dacian conquest. No. 12 is another fine Roman bronze. It is a statuette of Apollo, still standing upon the original decorated bronze stand. There is an inscription punctured upon the back: "M. Port. Tert. Bel. Aug. Concord." By far the finest antique in the whole collection is the lovely Venus in Case 5, No. 165. She stands nude, and holding a wreath, 13½ in. high. The late Professor Westmacott attributed it to the School of Praxiteles, a conjecture highly probable both on account of its excellence and its having been found in the neighbourhood of the ancient Stratonice in 1811. Praxiteles worked in Caria. No. 76, a figure of a Greek warrior, the right arm and half of the lower limbs wanting, is good, and is covered with a fine green patina. The most important

statue in point of size, as well as for interest and excellence, is David (No. 78). It is supposed to have been executed from the design of Michael Angelo by one of his pupils. The Duke of Westminster shows a fine bust on a bracket by the mantelpiece, the life-sized head of a young girl, of the early part of the 16th century. The Rev. Montague Taylor has many Florentine reproductions from the antique, among which are, No. 17, an elegant figure of Ceres, reduced from the original in the Vatican, much resembling some of the charming coloured terra-cottas discovered in Boeotia; No. 1, a group of Silenus carrying the young Bacchus in his arms. This is said to be a reduction of the fine statue in the Louvre. The original work from which the several antique statues of this subject were copied is believed to have been lately discovered in the excavations which have been going on at Olympia. Of the celebrated Borghese Gladiator of Agasias there are no less than three Italian copies, Nos. 31, 329, and 331; all are good, but by far the largest, oldest, and finest is the last, which belongs to Lord Elcho. The original marble of this is also in the Louvre. Some very fine groups and statuettes are placed upon the tables in the centre of the room. There is a very satisfactory antique bronze of a bull, lent by Mr. Bowyer, finely modelled and very highly finished; and close by a delightful full-length figure of Venus, with her arm upraised, belonging to Mr. Fisher. No. 411, "Hercules and Antæus," after Baccio Bandinelli, is full of vigour and power. Mr. G. Salting is the fortunate possessor of the beautiful group No. 323. Charity, after a design by Beccafumi, is represented by an erect figure supported by two children at her feet, while she carries a third in her arms. The bronze is in every way a most beautiful work. There are several examples either by or after John of Bologna, the crouching Venus, No. 333, being as good as any. It stands on a bracket to the right of cabinet No. 8. We must not omit to mention No. 159, a very fine Hercules raising his club, similar to Sir Richard Wallis' boxwood figure, which has the inscription "Opus Francisci Aurifeis." Bacchus, also, belonging to the Rev. Montague Taylor, on a bracket to the right of cabinet No. 1, should be noticed. There are a few, and only a few, interesting bronzes of sacred subjects. No. 168, St. John the Baptist, is upon somewhat slender grounds attributed to Donatelli; Nos. 161 and 163, St. John the Evangelist and the Blessed Virgin, to Lorenzo Ghiberti, though they seem too coarse and clumsy to be the work of that consummate artist. The crucifix, No. 260, which originally belonged to Cardinal Pandolfini, and was bought for Queen Marie Amelie of France, is a work of extraordinary finish. The last three items in the catalogue are among the best of this kind. Nos. 548 and 550, Melchisedec and the Prophet Malachi, are both signed works of Alessandro Vittorino, and are remarkable for their dignity and the simplicity and correctness of their drapery. No. 519 is a powerful rough casting of a half-finished model of Pluto, holding a trident in his right hand, with the dog Cerberus at his feet; one of the Fontainebleau gods done in silver, by Benvenuto Cellini.

Among works executed for domestic purposes the knockers, saltcellars, and inkstands are the most conspicuous, with the exception of one beautiful bell, lent by Mr. Salting (No. 326). It is only 6½ in. high, but full of the finest work in low relief, of dancing children, with bands of floriated ornament; on the top is a boy playing a tambourine. Nos. 86 and 87, a pair of Sphingi, are finely decorated. The best of the knockers are Nos. 309 and 331. The former was taken from the Grimani Palace at Venice, and is formed of a very bold and well-wrought

mask supported by dolphins. The other, of which there is a replica, exhibited by Mr. T. Shattock, is ornamented by a fine nude figure of Neptune, with a sea-horse on either side, terminating in floriated ornament. The candlesticks (Nos. 169 and 175), lent by Mr. Drury Fortnum, and attributed, without much reason, to Pollajuolo, are excellent examples of the most skilful casting. The ornamentation of No. 169 is as sharp as the finest Wedgwood. No. 175 is simpler, but no less artistic in design and execution. There are many fine inkstands, a most beautiful specimen of which is No. 174, Pan, seated, holding a vase; and in the same case (No. 173), a very wonderful work, formerly in the Bernal collection. Two others (Nos. 164 and 166) are by Peter Viseher, the great Nuremberg bronze-founder, the author of the splendid shrine of St. Sebald, a cast of which may be seen in South Kensington Museum. They are neither of them very important specimens; No. 166 is the better of the two. The number of medals and medallions is very great. To many people the ease containing these smaller works will not have the least interest, containing, as they do, so many well-known portraits. Cabinet No. 6, all belonging to Mr. Drury Fortnum, holds a marvellous collection. In the centre there is the original portrait in wax of Michael Angelo, by Leo Leone. It is an excellent proof of the wonderful pains and care taken by the best Italian artists in perfecting the medals which so surprise us as real marvels of true portraiture. We have here both the medal and model. After this the most interesting things in this case are the plaques which formed the centre of paxes, among which Nos. 189, 190, 196, and 230 are worthy of notice. No. 231, a Virgin and Child, gilt, of the 16th century, is very fine. No. 248 is a portrait of the Saviour, said to have been taken from the emerald vernicle. All the table cases containing portrait medals should be carefully scanned. Both historically and as works of art the contents are of a very high value. Many are by famous artists, such as Pisano, Pasti, Sparadio, and Enzola. In concluding this notice of the bronzes exhibited, we must demur to the statement in page 6 of the preface to the catalogue, that we possess no works in bronze of the date of the finest period of ivory carving. The latter work, usually gilt, of the 12th to 16th century, is quite as good as the ivories of the same period, as for instance the splendid tombs in Westminster Abbey, the candelabra at Venice, the hundreds of fine monastic seals, lecterns, and other articles of church furniture *ad infinitum*.

The ivories would have been more generally interesting if they had been better arranged and classified, and more correctly described. The oldest is an Egyptian head, No. 290, of very archaic and somewhat tame character. No other example earlier than the 13th century A.D. is exhibited, except the plaque, 11th or 12th century, No. 266, on which is represented our Lord in the act of benediction with the four evangelist symbols at the corners, surrounded by the usual semi-Classical ornamentation; and Mr. John Malcolm's beautiful Hispano-Moresque box; which is covered with the usual interlacing foliation, and has a truly Oriental inscription round the edges in Cufic letters, in praise of its own beauty. The same gentleman contributes several other leaves of diptychs and triptychs of high quality. No. 281 is a diptych, with the life of Christ in six compartments under handsome canopies—some containing two subjects, as the Betrayal, and subsequent suicide of Judas. There is more life and spirit in parts than we usually meet with. No. 274, a leaf of a diptych represents the death of the Virgin, in three compartments. The lowest gives the chamber of death, with the apostles showing violent signs of grief; in the middle she is

being carried up to heaven by angels; while one on each side carries a candlestick, others are censuring and playing instruments of music; at the top is her Son carrying her soul, like a little child, in His arms, the heavenly host standing round with harps and other instruments in their hands. The finest specimen of Gothic ivory in the room also belongs to Mr. John Malcolm. No. 282 is a wonderfully fine leaf of a diptych, 9½ in. by 5½ in., alike important for size, execution, and condition. It still, fortunately, retains the delicate original decoration in gold and subdued colour. The Rev. J. C. Jackson, among other interesting things, has sent a very pretty polyptych of five leaves. On the outer shutters are prophets and Saints. The centre tabernacle, divided into two compartments, has Christ in Majesty at the top, and the Virgin supported by angels in the lower one. The terminal piece of a rosary (No. 287), of Early 16th Century German work, is a remarkable instance of realistic treatment. Mr. Fisher has lent a perfect rosary (No. 337), with a somewhat similar ending to it. The description given is that there are three faces, Our Lord's, that of the Madonna, and of Death. We think by comparison with No. 286 that the lady's head is that of the wearer, a *memento mori*; that No. 287, in fact, belonged to a man; Nos. 286 and 337 to ladies. The collection of Mr. P. C. Hardwick contains examples worthy of high praise, from the 13th to the 18th century. No. 94 is a good ceremonial comb, French, of the 15th Century, with religious subjects. The Virgin and child crowned (No. 100) is signed Bianchi and dated 1507. It is seldom we are so fortunate as to meet with dated or inscribed ivories. There is great grace and elegance in this beautiful figure. The drapery is singularly bold and simple. Of later work, in the style of Fiamingo, we have a plaque (No. 103), with a tiger drawing the infant Bacchus, surrounded by baby bacchanals. No. 110 is one of the best Italian 17th Century works. It is called Mars, Venus, and Cupid, but more probably represents Hercules and Omphale; the feeling is distinctly Roman. The perfection of rococo treatment is shown in the statuette of Prometheus of the 18th century. The exhibition is richest in the works by and attributed to Fiamingo and his school. No. 113, a cast of the splendid Bacchanalian subject by him at Madrid, shows how impossible it is to accept the authenticity of many works, even in these rooms, to which his name is attached. It is exhibited by Mr. Alfred Morrison, who also sends No. 296, the model in wax of Silenus on his ass with the attendant train of bacchanals. Cabinet No. 2 contains some of the most interesting examples of this kind. No. 67, a sleeping boy, from the collection of the late Mr. G. Field, is an undoubted Fiamingo. Two groups of boys, holding garlands of flowers and seated on roots of trees, 17th or 18th century, are very charming. There are several fine tankards in this case. Sir Julian Goldsmid's statuette of Venus castigating Cupid (No. 361) is capital; his plaque (No. 354), boys with goat, is a fine specimen of Fiamingo's work. Mr. John Malcolm's comb (No. 371), sculptured all over in low relief with the Massacre of the Innocents, is a work of high excellence. In No. 370 we have a faithful and skilful translation of a print by Hans Sebald Beham of the "Rape of Helen." Perhaps the most important ivory in the case is the "Triumph of Death," 15th century Florentine work, reminding one of the earlier tapestries at Hampton Court; the tumbler of death, drawn by two solemn oxen, is levelled all alike, from the Pope to the peasant girl. The execution is in low relief, highly foreshortened; it is a very characteristic work. We thought that it was an established fact that the articles such as Nos. 378 and 379 were not nutmeg-graters as de-

scribed, but Rappee snuff-graters. In the first place the receptacles at the end are not large enough to take a nutmeg, and in later examples there is no separate place for what had to be grated, only a certain amount of room between the lid and grater, probably to hold a slab of compressed tobacco (Cavendish). We have a fine example before us in damascened steel, belonging to some French marquis of about the date 1730 or so, which has an inscription to the effect "Take a pinch. It is good." There is scarcely a doubt that these ivories were the original snuff grinders. It is curious what good work was bestowed upon these implements, whatever was their use, as may be seen in Nos. 378, 379, and others.

The whole collection, both of bronzes and ivories, is full of interest, but we wish that either the one or the other had been more fully illustrated; of ivories, at any rate, there is no lack in the country, if the possessors were only sought out.

BUILDING LEASES AND THEIR EFFECTS.

WE have before now deplored the effect of leasehold tenure on the houses in our suburban districts, and the injury it inflicts upon honest building activity. It is impossible to shut one's eyes to the needless and ceaseless appropriation of land round London and our great towns by the speculative builder, to the detriment of all good building, the ruin and degradation of intelligent labour, and the debasement of art generally. The same result stares us in the face everywhere. As we have repeatedly urged, the public not only pays but suffers; and the extent of the mischief is spreading—not merely robbing us of our green fields, but depriving us of comfortable houses, and grieving our eyes with a hideous travestie of architecture divested of every true sentiment and feeling. In elucidation of this subject an able article recently appeared in the *British Quarterly Review*, which is now reprinted under the title of the "Ethics of Urban Leaseholds." If we cannot endorse every opinion expressed, the author has our good wishes in the cause he has espoused. If ever people are to be driven out of the suburbs of London, it will be by that continual aggression of the speculative builder which is defrauding the citizen of every spare acre of land that has a tree or a bit of herbage upon it.

Nothing can be more insufferable than the filling up with piles of dreadful brickwork every available piece of ground that the cupidity of freeholders or their lessees can turn into account. When we turn for a moment from the unendurable monotony of the localities thus given over to the greed of ground-landlords and lessees, to the process by which freeholds are converted into leasehold tenure, the system is still more pernicious. As the *Quarterly Reviewer* aptly observes, "leaseholds are eviscerated freeholds stuffed with law." Land soon became a rich harvest for the lawyer's cleverest devices. As soon as a freeholder found his land developed into building land he was prompted to turn it into account. A lawyer, and generally an architect, are concerned in the little business. They persuade him to develop still further its capabilities, they lay a plan before him, draw up leases, and pocket their fees. "Meanwhile," as the author observes, "the lawyers and the architects are realising what the man of property can only make his hope; they plan and litigate, as leaseholds need, and get their costs. The sewers and roads are also made at a large outlay, bringing no immediate return, but yielding a commission to the architect, and then the property is quiet for some years. At length a plot of land is let to a smart, enterprising builder, highly recom-

mended by his timber merchant; and to induce the builder to proceed with spirit and secure the ground-rents, liberal cash advances from the fortunate proprietor are suggested, and eventually made. The architect will certify the cost of building work to warrant each advance, and the solicitor will take the builder's equitable security and his receipt, the fees remaining with the architect and lawyer as before. The freeholder is once more good for all, but gets no gain. The work, however, does proceed with spirit. Possibly a dozen "carcasses" are soon in a condition for the first advance, and so they rapidly proceed till all are covered in; and then the builder, having gained his stipulated cash advance upon the maximum of rough material, to be paid for when his three months' bills are honoured, and on the minimum of costly labour which he has to pay for promptly in days' wages, can with cheerfulness look round him, and his friendly timber merchant being paid, he offers—and a liberal offer too—his general creditors 5s. in the pound. The creditors who know their business acquiesce, and, pocketing their dividends, are quite prepared to trade with the same enterprising builder on some other 'freehold property,' where 'cash advances will be made.'" The story, as far as it goes, is the old one; but the worst has yet to come. The work stops. The creditors of this class of builders do not lose; they insure themselves against the risk by extravagant prices, by giving large discounts varying from 20 to 50 per cent. But the freeholder is often less fortunate. His hopes of wealth are prematurely shattered, and he finds, to his dismay, that his land is only covered by half-finished houses, which have either to be finished or sold for what they will fetch. A great reduction upon the former rental is the result; "advances" are made more cautiously, or not at all; or, as in most cases, the ground rents are sold as fast as they are realised. In numerous instances the land is sublet; that is to say, the freeholder lets the land, with all its risks, at a nominal ground-rent, to a speculative builder, who, by underletting himself, makes "improved ground rents." Anyone who is experienced in this sort of business knows that it is, at best, a rotten one. The builder becomes bankrupt, the mortgagee who advances to him money becomes the possessor of an ill-constructed row of houses, and the public complain, but suffer. In every instance the tenant, and not the builder, is the loser. When to this loss is added the heavy costs of lawyers and surveyors, the percentage of tradesmen, and the cost of bad labour, the leasehold house system, as our author says, becomes the most extravagant one we can conceive. We see miles of unfinished houses in every suburb of London, the results of the system being wasted material, uselessly-applied labour, and public discomfort. It is needless to describe here the kind of houses constructed upon this system. They cannot be called "homes," for, as the writer points out, the rooms are uncomfortably small in many cases, and are crammed with a class of tenants worthily called "lodger tenants," which compose the larger half of suburban London. Nor has the freeholder the control he imagines; his freehold ground-rent is but leasehold in value, while the reversion of the buildings is a mere figment, of no value whatever during his lifetime at least. There is a mistaken idea in the value of a reversion that most people fall into, and which can easily be shown if they give themselves the trouble to consult the interest tables, or make an easy calculation. To make this clear, the present value of the reversion of an estate after, say, 40 years is worth only one year's purchase, and after 60 years only a quarter year's purchase. The reviewer points out a fact patent to every dealer in property, though unknown to a large class

of lessors, that of two plots of land of equal size and value, the one sold realises at least one quarter more than the ground-rent of the corresponding leasehold lot built upon. In one case the freeholder may get (supposing each plot is worth £90 a year) £22 10s. per annum increased income, and in the other, the leasehold, only 22 weeks' rent, but which really has no commercial value, having, perhaps, 60 years to run before it becomes his property.

But the leasehold system is not only a losing game so far as property owners and tenants are concerned—it is pernicious in its effects upon the thrift of the small capitalist. Many industrious working men, who have saved a little and have become leaseholders, have been ruined either pecuniarily or morally. Often they become bankrupts; quite as often, we fear, the instruments of seamping as they are the results of the system. A great charge is brought by the reviewer, and not altogether unjustly, we think, against the working builders of London. We are told "not one quarter of the working builders about London are efficient tradesmen worth their wages. All the rest are spoiled, or have been grievously arrested in development by sub-contracting, and the present architectural and leasehold systems." The assertion has some foundation of truth; it is no less true, as admitted in another place, that speculating builders are not half so much to blame as their accusers, and are the "result of public folly." The measure of public taste is soon perceived by them as it is in every other kind of supply, and a builder, like the provision dealer or the tailor, supplies the article most in request. "As a class, certainly they are not culpably successful at the public cost, nor are they so beholden to mankind that they should sacrifice themselves to architectural philanthropy." And here we must reiterate the truth that the ordinary occupant is supremely ignorant of what affects his own or his family's health and comfort in the matter of house-building. Houses are built to look at, to appear "superior to their rental," and they reflect fairly the popular taste and requirements.

The reviewer ably shows that the leasehold house acts and reacts injuriously upon the public: it induces flimsy-mindedness and increases the unrest and mobility of the London population. Commencing with a "perfectly genteel idea, they wear their spurious gentility, a robe of Nessus, all their lives. It is the elegant and showy leasehold house that starts them on their life-long painful and unfortunate career." Tenants are a migratory class; they take a house for three or more years till, from neglect on the landlord's part, it becomes quite uninhabitable through want of repair and paint, when they leave for another house to make another move when it becomes too dirty to endure. Again, it is argued that intellectual growth and mental character are injuriously affected by this tenure; people become irresponsible, self-respect is lost, and trivial matters absorb the attention. Houses are so cramped that peace and comfort is sought for in places of public amusement, and fathers and sons betake themselves to the public-house. At least one half of the London houses are unfit for human habitation; they are either too small or too mean to live in; and all ranks of society are injured by them; west-end residents with their "compo-fronted" slips of leasehold work, as well as City clerks. "A nobleman," says the author, "till lately had a dual residence between the river and Trafalgar-square; the house has been pulled down, the site has been converted into 'frontages,' and now his Grace finds shelter in a narrow leasehold tenement that faces a cross-road behind the Queen's back garden."

In short, to the leasehold tenure is attri-

buted the chief cause of improvidence among the working-classes, the weakly, dwarfish stature of Londoners as a rule, and their enervated intellect; but we proceed to examine the remedy suggested. It is that by a weekly payment a visible investment may be secured to the working-man, in a freehold of his own. At present it is true "the inhabitants of London have no pride or satisfaction in the place; they only wish to make their fortune by its help and then to get away from it as soon as possible." "It is the first essential for efficient action," we are told, "that freeholders should be both taxed and represented, and that by some equitable system of land transfer those who are the subjects of taxation should obtain possession of the soil in fee. . . The ultimate proprietary leaseholder with more than 20 years of unexpired term should have a legislative right to purchase, at an equitable valuation, all superior interest, including the fee simple of the land; all titles should be registered and Parliamentary, and transfers should be prompt and inexpensive." Such a reform could certainly be done with little disturbance of present rights. The estates of corporations and charities may be sold with preference for the leaseholder, and the proceeds invested in the funds, by which means the land would be turned into profitable account by individual freeholders, the interest in the land would be enormously increased, and the public would be gainers by the greater care bestowed for public works. Private rights are now fenced in, to the exclusion of public enterprise and individual exertion; the expropriation of house property is called "communism" by one set of critics, as the author observes, but the same principle has been lauded by these economists when proprietors have been forced to give up land for the public good. In the interests of art, the change from leasehold to freehold would be material. No one will doubt that leasehold is the cause of all bad building; it is the invention of the present age, and our architecture has reflected the change. We have only to turn to our grand mediæval structures built on freehold land to observe the effect. In conclusion, we are tempted to quote the author's allusion to the subject of architecture. Of it, as an art, he says, "the public are entirely ignorant. There is some small scholastic and still smaller antiquarian knowledge, which gentlemen occasionally demonstrate at institutes and architectural societies. With such persons architecture is a luxury, a fine art for superior people to design and criticise; and to amuse these people, and the public who accept their dicta, millions annually are spent in travesties of art. On every other question that affects their daily lives it is supposed that Englishmen are apt to form an independent practical opinion of their own; the art of building, then, should hardly be excepted. They reproach the 'architectural profession' not discerning that their own neglect of homely art has made this counterfeit profession possible. . . . As the public grow more wise they will repudiate vain ignorance of building-work; they will at all times recognise its dignity, and, with delight, they will appreciate its value and its power." It is absurdly unreal to become a passionate admirer of antique art when everything is barbarous at home, and we can heartily appreciate the words of John Stuart Mill, that "nothing contributes more to nourish elevation of sentiment in a people than the large and free character of their habitations."

The nave of the ancient church of St. John, at Abbridge—which has some remains of workmanship of the 13th century—having undergone thorough restoration, was formally reopened on Monday. The cost of the works carried out amounts to £3,000. Mr. J. D. Sedding was the architect.

MELROSE ABBEY.*

MELROSE, like Tintern, has a host of admirers, though among this number there are many who know the ruins more by reputation than from personal examination of them. There are few, probably, of these who have not become entranced with the abbey from Scott's glowing description, who has, however, thrown around it a tradition hardly warranted by the bare record we possess. Measured drawings of historical buildings are always welcome as supplying a desirable link between written records and the building itself, and we have upon our table a new work upon Melrose Abbey Church, by Mr. Fredk. Pinches, A.R.I.B.A., consisting of measured drawings chiefly made by the author during the summer of 1878, and which obtained the silver medal of the Institute of British Architects. The work consists of ten photo-lithographic plates of large folio size, and illustrate the abbey church in a fairly complete manner. A good plan is given, well figured, with dimensions, from which we observe that the total internal length to wall of sanctuary is 245ft.; the width of nave, including aisles and chapels, 69ft. We should have preferred a little bolder style of figuring in the leading dimensions. Our readers are aware that the conventual buildings at Melrose, unlike many other examples of Cistercian abbeys, are on the north side; and this and other peculiarities have been pointed out by Mr. Walcott. Mr. Pinches says:—"The chantry chapels on the south side of the nave I am inclined to think never belonged to the original church when it was destroyed by Edward II., and afterwards restored with Robert Bruce's grant." The author thinks the restoration proceeded as follows:—"The screen was built and choir continued up to the eastern arch of the crossing, and choir inclosed from pier to pier on south side (and perhaps on north) with a wall, and this was the church which was used, the altar being placed at the crossing whilst the rest of the building, including sanctuary, chapels, transepts, &c., were being carried on." One irregularity which supports this view is that the south wall of south transept is not parallel with the rest of the church. The restoration proceeded very slowly. The south elevation is very carefully drawn in line, and no attempt at shading has been attempted—a desirable omission. It shows the beautiful Decorated tracery of the chapel windows and the rich window of transept, with its series of gable canopies and corbel steps; the bell turret in centre belongs to the Presbyterian era. The peculiarities in this part of the structure are pointed out by Mr. Pinches, such as the door in south transept and the unevenness of the masonry in parts. We must remind the reader that the original church founded by King David I. in 1136, according to the "Chronica de Mailross," was almost wholly destroyed by Edward II. in 1322, and that the present beautiful building was erected at intervals between that date and the Reformation. There is no wonder, then, that the details of many parts exhibit variations which the lapse of time had created. In 1385 the abbey was burnt by Richard II., and from this time the style of Scotch architecture became somewhat Continentalised, and the author believes that from about this period to 1512 arose all the work of the south and east fronts. There is certainly a touch of Flamboyant work in the windows of the sanctuary which is of clearly Late work, and this portion of the ruins will well repay the student for the evidence of a combination of French and English detail. The buttresses are panelled and gabled and the label terminations and curves are especially fine. Of course, the gem of

* The Abbey Church of Melrose, Scotland, illustrated. By FREDERICK PINCHES, Architect, A.R.I.B.A. London: Shaw and Sons.

the building is the sanctuary window, filled in with tracery of particularly unique character, in which there is not a single curve visible in the work, if we except the cusping, the lines being all rectilinear. The author gives a restored elevation of this window, showing also the crow-stepped parapet with its openwork of quatrefoils, of which only one at the bottom, adjoining the pinnacle, remains. The canopies of niches have a diaper-pattern carved upon their soffits. The figures on the apex, under the curved portion of label, are supposed to represent King David, the founder, and his wife, but Mr. Pinches thinks, from the time that had elapsed since the foundation, that they are more likely intended for James IV. and his wife, who were married at the church, and who greatly aided the restoration during his reign, 1488-1513. Unfortunately, a great deal of the carving, which is of great delicacy, has been subjected to rough usage.

We find that the screen, like that of other abbey churches, has been a fruitful source of controversy, some contending it to have been the great organ-screen and others a rood-screen. Mr. Pinches supports Mr. Walcott in the latter supposition, and, from the evidence of position and date, we think it must have been a rood screen. We detect here a small clerical error in describing it to cross the church in a line with east wall of No. 7 chapel. The plan shows it to be that of No. 5. All visitors to Melrose must deplore the clumsy square piers upon the north side upon entering the choir, which were built against the original pillars, and which carry a vault of clumsy oviform shape of rough masonry—this work was done in 1618 for Presbyterian worship. The only part of the groining to choir that remains are the springers. The tower arches and piers of the crossing are fine, and the carved caps to pier on the south side and those of nave, given in plate 8, extremely interesting as examples of conventionalised foliage; in this case it is suggested by the Scotch or Curly Kail. The detail of bay in north transept, of which an elevation and plan are given to a good scale, is extremely interesting; and Mr. Pinches' monograph is rendered additionally interesting by the sketches of details given in plate 6, the chief fault we have to find being that the shading in some instances quite spoils the work, as in the label terminations.

We are rather sorry better interior views do not accompany the details. The view of north transept would not have suffered, from an architectural point of view, if the shading had been omitted, and we should prefer plain outlines to the carved details on plate 4. Mr. Pinches has wisely, on this account, contented himself with giving the architectural features mainly, and has avoided the illustration of the carved work. The vaulting to the aisles is not illustrated we find, and is the exception to the above remark. Few remains are so rich in the adaptation of natural foliage as those of Melrose. Flowers and plants of the simplest kind have been studied by the carver, amongst these being imitations of rose-leaves, thistles, ferns, oak and ash. The volume is prefaced by a rather bare historical sketch, the style of which scarcely does the draughtsmanship justice, though the author has consulted some of the leading authorities, chiefly the "Chronicle of Mailross," which gives an account of the abbacy from 735 to 1270, from which we learn that the abbey was finished in 1136 and dedicated in 1146. Of the original pile little is said and nothing that is certain, though Aidan is supposed to have founded it about the middle of the 7th century, and this structure, now called "Old Melrose" stood about two miles below the modern abbey. Mr. Pinches' volume is handsomely

got up, and dedicated to the Duke of Buccleuch, and is certainly the most carefully prepared monograph of the abbey we have yet seen.

SAINT ETHELREDA'S CHAPEL, ELY-PLACE.

FEW people are aware that close to Holborn may be seen a small, but as pure and as beautiful a specimen of Mediaeval architecture as either Lincoln or York Cathedral itself. The church of St. Ethelreda, in Ely-place, was on Monday last reopened, after a thorough restoration, undertaken by the Fathers of Charity. The chapel in Ely-place was, as many of our readers are aware, a portion of the London palace of the Bishops of Ely, and was dedicated to Ethelreda, a daughter of the King of the East Angles, who was canonised for her virtues, and who founded the great religious house at Ely. The episcopal buildings, with the exception of the chapel, were demolished at the latter end of the 18th century, and in their place the present houses, in the sombre brick style of that period, were erected, forming Ely-place. The chapel itself was saved, but suffered from the characteristic apathy and indifference of the age. It was long known as Ely Chapel, and was used as a place of worship for a Welsh congregation. At that time the grand east and west windows were blocked up, and the beautiful tracery all but destroyed. The little fabric was choked with dirt and whitewash. Early in 1874 the building was sold under an order of the Court of Chancery, and was purchased by the Rev. Father Lockhart for the Fathers of Charity, who, with most praiseworthy energy commenced the present restorations. The chapel is a small parallelogram, about 80ft. long by 30ft. wide, and 50ft. from floor to apex of roof, below being a crypt of the same dimensions. The walls are divided into seven bays by a beautiful and delicate arcading, five of the wide bays having windows of Decorated tracery, which have recently been restored from the single example that remained at the eastern end. Not long ago, indeed, the window openings were filled with sash-frames, and a portion of the tracery was found in the brick wall of an adjoining house. We now see this unique chapel as it appeared probably in its primitive condition. The whole of the unique wall gablets between the windows have been restored where defective, and together with the window tracery produce an effective arcading on each side. The gablets are acutely pointed, and rise to the height of the adjoining window arches, whose inside drop mouldings form the continuation. Their heads are filled with light tracery, consisting of trefoiled cusping, and are enriched by crockets and finials. The carved stone corbels in the spaces are to have statuettes, as originally intended. The windows are two-light, and each consists of cusped heads and trefoil, with a cusped sexfoil in the apex. The jamb and mullion shafts have delicately carved foliage capitals, and the manner in which the stonework has been executed is everything the most conservative restorer could desire, the sections of the mouldings and tracery having been carefully taken from the remaining fragments. These side windows have been filled with plain toned glass, with the exception of the south-east one, in which stained glass of a Geometrical character, yellow in tone, has been inserted. Two bays at the west-end have merely the blank cusped tracery to relieve the wall surfaces. Turning to the two fine windows at the east and west ends, we find the same care has been exercised in their restoration. Architecturally, they are too well known to need description here, and we have already illustrated them, together with other details of the church, in the BUILDING NEWS of June 1st, 1877, page 538, Vol. XXXII. The great eastern window has been filled with stained glass at the expense of the Duke of Norfolk, at a cost of £2,000. Figure subjects occupy the five main lights, while the three larger circles in the head have been also filled with figures. The colouring is bright, of considerable depth of tone, and we believe the design has already given rise to criticism. We must confess, a little less crudeness in the colour would have assisted to give value to a window of Geometrical design, unsurpassed, if it is equalled, in this country. As it is, however, the artist, Mr. Saunders, of Endell-

street, has exhibited a considerable amount of skill in not making the figures obtrusive, and in following good precedents in the style; and his window at the side must be pronounced exceedingly rich and harmonious. The new altar is of stone, and has been designed with much discrimination from old models. It consists of a plain bevelled slab of stone resting upon side piers of octagonal form, having angle shafts, which stand upon a plain moulded base. The caps are characteristic of the style, simply moulded. Upon the altar stands a richly-designed alabaster throne and tabernacle, canopied for cross, and adorned with pinnacles and gables, and the whole has been executed with considerable feeling and skill. The roof of oak has been exposed to the framed rafters, and is of plain barrel-polygonal shape, with moulded tie beams, king-posts, and braces. Its brown massive timbers form an agreeable contrast to the Caen stone ashlar walls. The seats are open, with square bench ends, and a new organ is placed on the north side of the chancel. One of the most interesting relics of the older chapel is the Saxon font. It is of Purbeck marble, and consists of a plain circular bowl with four rib-like projections on the out-side, and now stands on a circular stone base. There are few examples of Early English doorways which surpass the main south entrance to this chapel. The three-jamb shafts have been carefully restored and the mouldings now look as sharp as when first cut. An illustration of it appeared in the BUILDING NEWS of the date we have mentioned. The sedilia still remain. The stone used for the shafts and tracery is Stoke Ground from Chippenham, a very hard limestone. The material of the old walls was Kentish rag. On the outside we observe that the octagonal turrets which flanked the eastern front have not been restored, though the bases exist. The irregularity of the masonry at once discovers to the critical eye this omission, and we hope when the funds permit they will be carried up and be crowned with the conical cappings which once so agreeably finished the gable ends. The crypt below has also been restored.

The solemn re-dedication of the chapel was performed last Monday by Cardinal Manning. The work has been carried out under the careful superintendence of Messrs. John Young and Bernard Whelan, architects, by Mr. M. F. Doherty, contractor, of Blackfriars-road. It has, we think, been done thoroughly, and with a conscientious regard to the old structure.

MODERN ART FAIENCE.

THOSE who are interested in faience and decorative art will find the museum of Messrs. Trollope and Co., of Halkin-street, Belgrave-square, well worth a visit. Under the able art directorship of Mr. G. T. Robinson important acquisitions have been made, chief among which must be mentioned some choice decorative earthenware of foreign manufacture, in which the two hitherto irreconcilable elements of artistic design and moderate price are combined. It has been the main object of this enterprising firm to show that common clay wares may be treated both decoratively and inexpensively, and with this purpose in view they are now exhibiting some exceedingly artistic products in the commoner kinds of material. We especially draw attention to the Swiss and Hungarian pottery, not only for the beauty of the designs, but for the colours and glazing. Many collectors of art pottery would be surprised to find that the modern art labour of Continental countries can still produce works of artistic design and excellence, and they would be obliged to admit that only a mere passion for antiquity would induce them to purchase old ware. The Swiss pottery is particularly rich in colour. Generally a dark brown or black ground is given to the body, upon which flowers and foliage of bright colours are painted highly glazed. The body of the vase or piece is well covered, and the design has a very rich effect. Some beautiful specimens of this ware are to be seen in Messrs. Trollope's Museum, comprising vases, bowls, and other ornamental kinds of pottery. The French glazed ware forms a unique selection. We noticed some charming vases of deep blue, green, and other blended colours, the work of a comparatively obscure artist whom the artistic discernment of Mr. Robinson will doubtless bring into repute. For delicacy of manufacture and

refinement of design the Hungarian and Austrian examples are unsurpassed. These have a white body of pipe-clay, upon which the designs—Persian in character—are painted in blue, and gold, red, maroon, and other bright colours conventionally treated, though with considerable freedom. We noticed a collection of beautiful and delicately covered vases, dishes, and plates of this ware; some exceedingly simple and inexpensive plates, painted with figures in outline. One dish we noticed with a very effectively simple design in outline was only 5s. 3d.; another set of four pieces was 15s. 6d.; two charming plates, with figure subjects drawn in blue outline, 5s. each. A pair of handsome blue and white fruit dishes, with a very rich embossed design and borders, were equally cheap. The geometrical and floral patterns upon some of the more elaborate objects are extremely delicate and truthful. The borders are in some instances plain bands of blue, in others of Oriental intricacy, and the case of blue aster ware is deserving notice. A pair of large dishes of Hungarian manufacture, in a rich brown body colour, have an engraved border of very telling effect; the engraved portions remove the dark colour and produce a tortoise-shell appearance to the parts scooped out. We notice also of Austrian design a very well designed flower-stand or fountain of terra-cotta, coated with a rich glaze of a deep bluish-green hue, and admirably adapted to adorn a conservatory or a hall. Modern Italian faience is illustrated by some beautifully hand-painted vases and other objects, with figure and allegorical subjects upon white grounds. We observed several beautifully designed vases, copies from the antique, exceedingly spirited in design and rich in colour, the work of Castellani. Blue and yellow are the predominant colours, and the painted dishes and plaques are admirably suggestive of ancient work. We must not omit to say that the once-forgotten metallic lustre ware may be seen in some beautiful Florentine pieces; a few plates with blue designs on a gold or bronze ground being very striking. One pair have emblematic figures in the middle with musical instruments, another with the head of Petrarca. The specimens brought together by Mr. Robinson are marked by considerable excellence as works of art, though they all exemplify what can be done by simple methods of decoration upon the common earthenware. The sgraffito treated glazed earthenware is very suggestive in this way, so are the lava painted panels. But we wish to draw the attention of our architectural readers to a few more special exhibits. Of a utilitarian kind we must mention some terra-cotta glazed tiles for back buildings and decorative roofing purposes. These consist of plain ornamental tiles of lozenge and other shapes, with an indestructible glaze upon the surface, which may be produced in grey, red, and various colours. For reflecting light in areas and courts we believe there is a large field open for the use of these washable and impervious tiles. We must mention also some well-designed and modelled terra-cotta pilasters in slabs for decorative brickwork. Those we noticed were 9ft. in height, and of proportionate width, and were £6 10s. the pair. The design was Renaissance. Of sanitary appliances, we must call attention to some excellent nickel-lined copper baths. The one we saw had an improved arrangement of taps and mixing cylinder. The advantage of the material is that it is self-cleansing and indestructible, and the bath has no unnecessary casings. A shower and spray bath, with taps and pipes of nickel, is the best of the kind we have ever seen. Every part of the body can be subjected to the shower jet or spray, and the hot and cold water can be regulated, mixed, and directed with the greatest nicety and ease by the patient himself. The latter is priced at £66.

We may draw the attention of architects to a highly decorative kind of relief panelling in gesso, the revival of an old process, which Mr. Robinson has introduced. A door of mahogany treated in this manner with its panels decorated in gesso and gilded, having ebony and gilt mouldings, and the effect was striking and rich. Another mode of decorative finish deserving the notice of the profession consists in a kind of Japanese laquer panels, and a beautifully-executed series of panels treated in this manner for the Cunard Line steamer *Gallia* is now on view. The Mexican onyx is a very beautiful feature to be noticed in this museum. We particularly call attention to the semi-transparent chimney-pieces

partly and entirely made of the onyx; also a balustrade, the cost of which we believe per foot when highly polished is £15. The Mexican onyx is a remarkably hard material, and its sea-green transparent and opaline tints are of the most charmingly varied kind. As a valuable decorative application upon this material we notice a panel of onyx with a relief ornament in gesso, and we think as an interior mode of wall and panel enrichment the process is likely to become one of much beauty and utility.

A WHOLESALE JAPANESE WAREHOUSE.

THE name of Dr. Dresser has long been very well known in connection with ornamental design, and he is the author of several popular books on the subject, some of which are of a costly character. During the last few years Dr. Dresser has travelled in Japan and the East, making himself practically acquainted with the manufactures for which the Orientals are famous, and one result of these trips is the large and varied collection of goods with which Dr. Dresser, in conjunction with Mr. Holme, has stocked the large warehouse which was last Saturday opened to private view in Farringdon-street. The building thus occupied is the singular and striking house erected by Mr. Hyatt, the patentee of the prismatic area lights, and here the several applications of his patent are shown throughout the building. Messrs. Jackson and Graham, under the direction of Dr. Dresser, have decorated the interior of the building. The want of a good staircase above the first floor is a very considerable defect in the arrangements. The stock above referred to consists chiefly of purely modern Japanese and Indian productions, such as the common Owari blue ware, in vases, flower-pots, and plates, which particularly lends itself to decorative purposes as well as domestic use. The Kishin lacquer trays and cabinets and Japanese basket work also are available for these uses. The Awata and Tokio ware are both imitations of Satsuma ware, which is itself called by the Japanese Tsuchi-yaki, or clay ware, to distinguish it from porcelain; and these deserve notice as quiet and yet richly coloured faience of creamy tone, not of course equal to Satsuma, but sufficiently interesting for ordinary purposes, and within the means of moderate purses. Some of the Tokio ware, however, is much more rich in colour and gold, and is made in large and expensive pieces though always refined. The silver and ivory work of the Japanese are of course among their more famous productions, and these are largely represented at Farringdon-street. The same may be said of translucent enamels and cloisonné on metal, of which there are many beautiful examples. The Bombay ware, though coarse in detail, is very soft in general effect, and devoid of the harsh colouring of the yellow and gay green characteristic of the Scinde manufacturers. The Kioto ware teapots are curious as well as varied in form, and the collection includes several specimens of old Persian brasswork, and also a quantity of Moradabad metal ware, with the silver-like chased tin products from Lucknow. On the third floor Dr. Dresser's curios are located, but only a small selection of these were shown on Saturday, including some antique turquoise Celadon vases, and another said to be a thousand years old. The top story of the building is used for a carpet showroom and store. In conclusion we have yet to note the entirely new Linthorpe pottery, which has undoubtedly much both in colour and design to secure its very general use as an inexpensive class of decorative pottery. It has been introduced by Dr. Dresser, from whose designs the articles are made, and most of the specimens are very successful, though there certainly is a tendency towards extravagance which it would be better to avoid. The brilliancy of the glaze is excellent, and almost any colour is obtained, the cheaper kinds being simply produced by dipping, though as simply a clay ware none can be well of a costly character.

THE ANNUAL REPORT OF THE METROPOLITAN BOARD OF WORKS.

THE volume annually issued by this Board recording the work it has carried out during the previous twelve months becomes each time a thicker volume, testifying to the increasing work laid upon this anomalously-constituted but ener-

getic Upper House of the metropolitan local authorities. That for 1878 is now before us, and deals with a wide variety of subjects. Under the heading of "Sewage and Drainage" reference is made to the way in which it is being attempted to obviate the floodings to which various low-lying parts of the metropolis are subjected on occasions of heavy rainfalls. These are in addition to the intercepting sewers, which were not designed to take the waters which fall during excessive rainfalls, such, for instance, as that of the 10th and 11th April, 1878, when an average of 2.64 inches of rain, or nearly one-seventh of the average yearly rainfall, was discharged over the whole of the metropolitan area within 19 hours. To intercept such a volume of water as this would, it is remarked, have necessitated intercepting channels of the capacity of rivers, and these would have been nearly empty except on occasions of extraordinary rainfall. During the latter part of the year just ended works have been in progress having the twofold purpose of relieving Battersea and the adjacent low-lying parts from flooding, and of providing an efficient outlet for the drainage of the district which lies to the east of the line of the southern high-level sewer. The contract for the new sewers was originally undertaken for the sum of £16,800, but, in consequence of failure on the part of the contractor, the contract was relet by the Board on the 9th August last to Messrs. Williams, Son, and Wallington, for the sum of £17,800. About 1,920ft. of the main sewer has been completed, and a further length of about 1,000ft. is in various stages of progress. Works of similar character will shortly be commenced in Kilburn, the total length of the two new sewers being about 1,230ft., and the diversion and covering in of the Stamford Brook, Hammersmith, was completed by Messrs. Nowell and Robson in July at a total cost of £4,685. During the year plans for about 44 miles of sewers, varying in size from 4ft. by 2ft. 9in. in brickwork, to a 9in. pipe, proposed to be constructed by vestries and district boards, were submitted to the Board; and, in addition to this, 458 branch sewers were connected with the main sewers under the superintendence of the board's officers. Reference is made in the engineer's report to the electric lighting experiments still being conducted by the Société Générale d'Electricité on the Victoria Embankment, and to the erection on the same Embankment, at Adelphi Stairs, of Cleopatra's Needle. During the year the important new line of thoroughfare from Old-street to Oxford-street was constructed and opened to the public, and there were commenced the new thoroughfare from Shoreditch High-street to Bethnal Green-road, opened for use early in the present year, and the Sun-street to Worship-street improvement (forming what the Board last Friday decided to name Appold-street), let to Messrs. Nowell and Robson, and now in progress. None of the extensive street improvements proposed under the Act of 1877 have yet been commenced; but the report mentions that the widenings at the Angel, Islington; Mare-street, Hackney; the Deptford Creek Bridge approaches; Camberwell-road, and Church and High-streets and Queen's-road, Peckham, have been selected to be first proceeded with; and that those at Tooley-street, Borough, and Jamaica-level, Bermondsey, will follow; and adds that for these several improvements a large amount of house and other property has already been acquired and cleared away preliminary to forming the widened thoroughfares on the sites thereof. Under the Artisans' Dwellings Improvement Act, 1875, one, the Whitechapel and Limehouse scheme, was at the close of the year so forward that tenders were invited for the paving works of the new streets; the Bedfordbury and Whitecross-street schemes were in a forward condition, and six others were in various states of preparedness. Two new schemes received the sanction of Parliament during the session of 1878, and three further schemes, dealing with areas in Wells-street, Poplar, Little Coram-street, SS. Giles and Paneras, and Great Peter-street, Westminster, were prepared and are now under consideration in Parliament. Other paragraphs of the engineers' report deal with the unsuccessful Metropolitan Water Supply Bills, the condition and overflows of the Thames, and the proposed high-level Tower-bridge, as to which two last-named projects Bills are now being considered in committee by the House of Commons. During the year sixteen applications

from vestries and district boards for loans of or permission to borrow elsewhere sums of money for purposes of improvement; of these loans sanctioned, £67,587 was for works of paving, £11,905 for sewerage, £2,987 for road and street improvements, and £1,800 for river wall, bargebeds, and repaving at Chelsea parish wharf. During the year the following railway bridges over and under public roads were constructed or altered under the superintendence of the board's officers:—Bridges over roads—Old Ford-road, Bow, by the Great Eastern Railway; and by the South-Western Railway, York-street, Granby-place, and near Aubyn-street, all in Lambeth; under a road, New-cross, by the Brighton and South Coast Railway.

The superintending architect's report to the Board commences with a summary of the Metropolitan Management and Building Acts Amendment Act, 1878, of which the first part relates to the width of roads or ways, whether highways or not, and regulates the position of buildings adjacent thereto; it also gives the Board a limited jurisdiction over existing theatres and music-halls, containing a superficial area of not less than 500 square feet, and enables the Board to make regulations as to the position and structural arrangements of theatres and music-halls hereafter to be licensed. By part 2 of the Act power is given to the Board, with the consent of one of Her Majesty's principal Secretaries of State, to make bye-laws for regulating not only the materials to be used in buildings, but also the preparation of sites and foundations. The provision contained in the Metropolitan Building Act, 1856, with reference to the recovery of dangerous structure fees, is also thereby amended. Under the head of District Surveyors, reference is made to two changes made in the year in the limits of districts. The metropolis is now divided into sixty-four districts, and during 1877 there were 24,288 building operations, for which a gross total of £40,349 8s. 6d. was received in fees. Fees amounting to £1,521 14s. 5d. were remitted or lost during the year 1877, and the office expenses of the district surveyors were returned as amounting to £8,748 6s. 5d. There is a considerable difference in the amount derived by way of income from the several districts. The gross fees received in thirty-four districts varied from £82 to £599. In one of these districts the receipts did not amount to £200; in nine the receipts were less than £300; in five less than £400; in eight less than £500; and in eleven less than £600 each. In twenty-eight other districts the receipts ranged from £620 to £2,704. It is mentioned that the whole of the river plots on the Chelsea Embankment have now been let. During the past year £52,559 was voted by the board towards the cost of local improvements contemplated by the district boards and vestries, and estimated to cost £106,898 11s.; and £38,804 14s. 6d. was paid on the completion of improvements being certified. The parks, commons, and open spaces now under the control of the board cover an area of 14,573, and cost in maintenance during the year, a net sum of £13,905, the chief item being Finsbury-park, £6,260, where a great deal of tar-paving, re-gravelling, and other works has been carried out; Southwark-park, which absorbed £1,980, and Victoria and Albert Embankments, £1,455. Under the head of Fire Brigade Stations it is mentioned that the new headquarter station of the brigade in Southwark-bridge-road had been completed; a new station erected on Shooter's-hill by Messrs. Hook and Oldrey at a cost of £4,945; premises in Chapel-place, Knightsbridge, altered by Mr. C. W. Reading, for £1,192, and a new station is contemplated at Greenwich, in Grove-street, in place of that in Blisset-street. During the year, 2,146 dangerous buildings were brought to the notice of the Board, of which 1,527 were dealt with by the Board, or after the cases had been heard by a magistrate; 140 were reported not dangerous; in 430, actions were still pending at the close of the year, and in all the other 49 cases the works were promptly executed by the owners. The report adds that at no period since the Board has had jurisdiction in respect of dangerous structures within the metropolis, has so large a number of cases occurred, or been so successfully dealt with as during the year 1878; out of the total of 2,006 dangerous structures proceedings had to be taken before a police magistrate in 398 cases; and in every case, without exception, these proceedings were successfully maintained.

THE RAMSGATE MARINE DRIVE.*

WE have received a small brochure written by Mr. Percy W. Britton, C.E., upon the Ramsgate Marine Drive, which deals generally with the question. Mr. Britton is a competitor, being the author of a design bearing the motto "Perseverance per se Vince." How far he is entitled to speak readers must decide for themselves, but he does so with the authority of one who has carefully studied the problem. As he observes, an award has been made and seemingly set aside by almost universal consent. Mr. Britton analyses at some length the requirements of the schemes that have been proposed, and observes of the first, to which the premium is awarded, that "it is far too costly to be taken into consideration," while the "second scheme provides for a continuous view of the chimney-pots of the town, and is calculated to ruffle the temper of those who want to get from either cliff by a decent road," while "all the premiated designs sedulously avoid being nearer to the front than is rendered absolutely necessary by the limits of deviation." Those who have examined the designs will substantially agree with these allegations, and we were astonished to find that the "front road" was avoided by the favoured proposals, notwithstanding that it offered a better promenade and other advantages we have already pointed out. Mr. Britton's plan certainly meets the requirements in a more desirable manner, if it does not give us the most pleasing line of curve. The road is kept to the front, but not too close to the harbour. The line it takes follows the direction of the Military-road, passes over the Crown Hotel site, and crosses Harbour-street on the level; it then makes a rather sudden turn at Albion-hill, which it diverts, cuts diagonally across Albion-place, and thence follows the boundary of Wellington-crescent on the eastern cliff. On the western side the road would overhang the brow of the cliff, being carried on brick arches and piers of 30ft. span built into the face of cliff from Nelson-crescent to York-street. The roadway is thus partly carried by a half-viaduct, and partly follows the existing levels in the centre of the town—a plan that at least has the merit of being economical in construction. Mr. Britton, referring to the instructions, observes that the condition that the road must allow of easy and direct access from either cliff to the main street and central portion of the town, has not been complied with by those schemes which provide merely a roadway from cliff to cliff, without regard to intermediate points. This is very true, and it is one point that of course ought to determine or assist in determining a plan. In one or two of the plans we have pointed out this requirement has been met by branch roads. Again, it is contended by the author that the viaduct scheme is not suitable for a promenade, we certainly think it partakes too much of the stilted and artificial to become a pleasant one. There is even a more important argument in favour of the front route to which we have before drawn attention: it is the necessity that will be created by it for sweeping away the existing dingy and flimsy old houses and cottages in the centre of the town. No one who has visited Ramsgate can regret to see removed the dilapidated and tenement-like class of property which occupies the hollow facing the harbour. At present this part of the sea frontage is a disgrace to the town. Access to the centre of town with means of easily reaching the sands are points that have to be kept in view, and it appears to us that the designs selected have not sufficiently taken them into consideration. Mr. Britton's proposition at least keeps in view the requirements and limitations of the Ramsgate Commissioners; it provides access to the town, and leaves access to the sands; it communicates easily with existing roads, and it preserves, what is quite as important, a natural and easy route between the opposite cliffs. We do not think a lofty viaduct scheme the best; it would always possess an artificial appearance, and would require to be treated with some architectural skill, to blend easily with the scenery. Those who are interested in the improvement would do well at least to read Mr. Percy Britton's sensible remarks, bearing in mind, however, the manner in which other designs have met the question. We can-

not agree that the designs, "Audacter et Sincere," "Front," and "Westminster," are so particularly destructive to property as the author required, seeing that the reconstruction required would be practically limited to the front and least valuable portion of the town.

LAMBETH PALACE.

ON Saturday afternoon, a large number of members of the newly-established St. Paul's Ecclesiastical Society, paid a visit to Lambeth Palace Chapel and Library, under the guidance of Mr. J. P. Seddon. The members assembled in the first courtyard, where Mr. Seddon gave an historical sketch of the palace. The original building, he said, was erected by Archbishop Baldwin, who obtained the site by exchange with other land in the Isle of Grain, with the then Bishop of Rochester, in 1180. His object was, that his proposed new church and dwelling should be at a distance from, and beyond the influence of the monks of Canterbury, who had prevented him from establishing a cell of secular canons in their vicinity. Baldwin then commenced a chapel at Lambeth, with the intention of making it collegiate, but his death in the Holy Land in 1190 prevented his completing his purpose. The monks of Canterbury, zealous lest the metropolitan see itself should be transferred to London, continued their opposition to the design, and prevailed on Pope Innocent III. to issue a bull commanding its abandonment. In 1202 it was agreed, however, that a church and establishment of not more than twenty Premonstratensian canons might be built elsewhere in Lambeth than on this site. Archbishop Hubert relinquished this project, but made Lambeth his metropolitan palace, and his successor, Langton, improved it. Archbishop Boniface, however, in 1216 was ordered by Pope Urban IV. to build and repair the house at Lambeth, and the chapel, which is the earliest portion of the extant buildings, is probably his work, though it is difficult exactly to distinguish the buildings of that prelate and his successors. The palace at that time consisted of a manor house of a form then customary, the plan being one with buildings surrounding three sides of a rectangular court open to and facing the river, inclosing a cloister. The present chapel formed the left projecting wing of this structure, having its western front and entrance doorway then exposed. What is termed now the guard-room, parallel to the river in the rear of the chapel, occupies the position of the central block, while the buildings which formed the right wing have been destroyed to make room for the library, &c., which extend far beyond the original site. The "Lollards' Tower" was built afterwards outside to the west of the chapel and abutting against it; it was erected in the archiepiscopate of Chichele, 1424-45. The present entrance-gateway of brickwork, through which the visitors had just come, was built by Archbishop Morton, about 1490, and Archbishop Juxon, who would ever be remembered in connection with the execution of Charles I., constructed the Great Hall, which for some years past has been converted into a library.

Passing into what was once the cloister, now surrounded by modern red brick buildings and offices, Mr. Seddon called attention to the ancient masonry of the south side of the chapel just visible over one of the palace buildings; the wall has, he said, been capped by Blore with a wretched battlemented parapet, behind which rises his high-pitched roof. Outside the chapel, in the apartment beneath the Lollards' Tower, Mr. Seddon resumed his description. This room was known, he remarked, as the Post Room, from the great octagonal oak beam in the centre supporting the framing above. Till Chichele added this tower, the beautiful west doorway facing the members was external, and could be seen from the river. As they saw, it had a semi-circular head, but all the details were of a pure and delicate Early English type; the combination of these with the rounded form was rather curious, but instances of such transitional use of old-fashioned features as the circular head in a new style were not unknown, and in this case it seemed to have been adopted to provide sufficient space for the beautiful five-light window above, new, of course, blocked up by the first and second stages of the tower. This arch was elaborately and well moulded in three orders, the third one subdividing it into two equal trefoil-headed

openings. The head and spandrels above these openings were pierced. The outer arch was supported on Purbeck marble jamb shafts, and in the centre of the doorway was a group of three columns of like material, forming the sub-division of the entrance. The outer arch has settled, and the voussoirs are a little out of place. Entering the chapel, it was pointed out that it consists of a simple parallelogram on plan of stately proportions, being about 72ft. by 26ft. clear internal dimensions, with walls 4ft. thick. Both sides of the chapel are divided by bold buttresses without, and corbels for vaulting within, into four bays, each filled by a noble three-light group of lancet windows, of a type which would remind members of what they recently saw in the Temple Church. At the east end is a series of five lancets corresponding with that now blocked up at the west end. All the windows have detached internal bearing shafts of Purbeck marble, with moulded caps and bases, and beautifully moulded arches above. He might mention that externally the side windows are comprised beneath single deeply-recessed arches springing from the buttresses. High up on what was the central light of the western window, Archbishop Juxon inserted a small oriel upon a semi-octagonal corbel, with an angel carved thereon, bearing a shield, on which are the Archbishop's arms; it communicates with the chief floor of the Lollards' Tower, which was probably occupied during service by some members of the Archbishop's household. Archbishop Laud refitted and adorned the chapel during his primacy, and erected the screen which now divides the building into chapel and ante-chapel; this is of oak, and is carved elaborately, but in poor and heavy fashion. All the quadripartite vaulting was the work of Mr. Blore, and he was sorry to say, is only executed in lath and plaster. When Mr. Burges was employed by Blore on the work there was enough of the old lines to admit of their being followed, although the mouldings are not equal to the original ones. Concealed by this vault is a tremendous roof, clumsily executed in queen-post fashion with great waste of timber.

At the trial of Archbishop Laud, it was alleged against him that he had "repaired the story of the windows by their like in the mass-book." The subjects with which they had been previously illustrated in painted glass were from the history of the world, from the Creation to the Judgment, but these had since been replaced by lights of plain stamped glass, and were partly blocked up. Recently this chapel has been repaired by Archbishop Tait, assisted by a committee.* It has been partially decorated with new stained-glass windows, and painting on the walls and vaulted ceiling of the eastern-most bay by Messrs. Clayton and Bell. This bay adjoins the domestic part of the palace used as a vestry, and an organ is being placed in the north opening in a portion of the palace used as a vestry. The east window was in a dangerous condition, and was cracked at the angles. It has been rendered secure and coated externally where needed with Portland cement concrete; if the unsightliness of this work can be excused at all it is because it is now only visible in a small courtyard of domestic offices. During these works a curious doorway and passage were found in the south side of the gable over this window, leading to the space above the vaulting. Beneath the chapel a very fine crypt exists, but it is partially blocked up with earth, and is now used as a wine-cellar. It is divided into two aisles of four bays by circular pillars, and has plain groining, supported at the angles by moulded corbels. The details, though less elaborate, much resemble those of the chapel above, and like it, the crypt appears to be all of Boniface's time. Although much has been done to rescue this chapel from the sad and degraded condition into which it had fallen, through the neglect of centuries, and the injudicious work done to it at the beginning of this century, much, said Mr. Seddon, remains to be accomplished. Some of the windows are yet partly blocked up, the vaulted ceiling, painted though a portion of it is, is but lath and plaster, beneath a mean modern roof, which is a source of danger from fire, and a disgrace to the age which erected it and permits it to remain; the crypt is half-buried and is used for storage purposes, the external walls and buttresses are

* The Ramsgate Marine Drive. By PERCY W. BRITTON, C.E. Leeds: Bernard and Co.

* A critical description of this work, for which Mr. J. P. Seddon was the architect, appeared in the BUILDING NEWS for May 10, 1878, p. 465, Vol. XXXIV.

terribly defaced and decayed, and the brick parapet walls are an eyesore from all prominent points of view of the palace and its surroundings. The construction of suitable stone vaulting to the chapel, with an appropriate high-pitched roof with the eastern gable surmounted by good stone copings and cross, are improvements so necessary and so urgently called for, that it is to be hoped that they will not be left for another generation to accomplish.

The members then visited the prison in which the Lollards were confined previous to their execution by burning. It is a small apartment in the top story of the tower, barely 12ft. square and 8ft. high. It is entered from the turret staircase by a double door, both well studded with nails and other ironwork, and lighted by two small deeply splayed lancets. The walls and ceiling are covered with stout oaken wainscoting, fully 1½ in. thick, and at intervals about 3ft. above the floor project a series of eight staples, on which are stout wrought-iron rings, 3½ in. internal diameter, to which the prisoners were secured. The walls and ceiling are scored with initials, names, and broken sentences, chiefly in dog-Latin, cut by the followers of Wyckliffe. At the top of the stone turret is a small, picturesque, hooded bell-cote of the 15th century, from which, and the tower-leads beneath, the visitors obtained a fine view of the river, the Houses of Parliament, the extensive palace gardens—actually larger than Lincoln's Inn-gardens, and yet scarcely known to exist by those who pass along the busy streets by which they are inclosed—and of the south-west portion of the metropolis. The members transversed a long gallery, and reassembled in the guard-room, now used as the state dining-room. It is a noble apartment. The roof is divided into four bays by large timber arches spanning the structure, and decorative arches of wood also support the wall plate, and arched braces the purlins above. The spandrels of the principals are filled with richly-moulded tracery. A modern panelled flat ceiling hides the upper part of the roof, which originally was open. Like the gallery, the guard-room is hung with a series of highly-interesting portraits of former occupants of the archiepiscopal see. Mr. Seddon mentioned that excellent drawings of the chapel and its details, and of the roof of the guard-room, are given in the valuable work by Mr. F. T. Dollman, one of the vice-presidents of the Ecclesiological Society, entitled "Examples of Ancient Domestic Architecture, Second Series."

The visit closed in the old hall, now well known as the Library, built by Chicheley, and chiefly reconstructed by Juxon, on the Mediaeval lines, but with 17th century details. The hammer-beam roof, in four bays, is an excellent example for its time, and closely corresponds with that over the guard-room; it is of oak, richly carved, and the trefoiled openings and heavy pendants exhibit curious examples of an attempt to imitate the late Gothic mode of ornamentation. One of the best features is the picturesque central lantern. Mr. S. W. Kershaw, M.A., gave an historical account of the library, which he said was founded by Bishop Bancroft, and was added to by Archbishop Juxon and others. During the Civil Wars, when the whole palace was pillaged, and turned into a prison and stable, the collection of books was removed for safety to Cambridge, from whence it was re-demanded by Sheldon, and housed, till within the last 40 or 50 years, in the cloister of the palace. It includes many early illuminated missals and other MS., a number of specimens of Caxton's printing, one of the so-called Mazarine Bibles printed by Guttenburg, a vast collection of historical pamphlets, especially of the time of Henry VIII., and many works on theological and civil law. He should be happy to afford any further information on any Monday, Wednesday, and Friday, on which days it is open free to the public from 10 a.m. till 3 p.m. throughout the year. Before leaving the palace the members expressed their thanks to Mr. Seddon, and also to Mr. Kershaw, for the information so pleasantly imparted.

LIVERPOOL ENGINEERING SOCIETY.

At the fortnightly meeting on the 18th inst., a paper was read by Mr. E. Cornish, on "The Management of Tide Work," in which the author described the plant necessary for,

and stated the precautions to be taken when constructing heavy masonry works in a tideway.

He commenced by stating that an important point was to ascertain the direction from which the heaviest seas came, so that the end of the work in progress may be as much sheltered as possible. Having determined upon the point to commence operations, the position of the well for draining the foundation trench should be carefully considered, so that the lines of rails for supplying materials may be brought in conveniently and laid with easy curves. The position having been fixed, the staving should be erected over it, so that the Goliaths or travelling crane may be used for sinking the well and fixing the pump. The well should be such a considerable distance below the level of the foundations of the work, to form a reservoir for the double purpose of scouring out the "lander," and quickly running off the water from the workings. The necessity of providing a blow lander was pointed out for letting the water into the workings to the level of that outside, to prevent the rising tide rushing in upon the "green" work, &c. The author recommended the chain pump for this class of work, having had one working for eighteen months without requiring any repairs, and that it should be driven by a belt in preference to gearing. He next considered the staving, stating that the cost of timber in piles driven was three to four times that of timber erected as runners, &c. In place of the piles being spaced at about 13ft. centres, he advised the adoption of 20ft. centres with double runners, as requiring less labour, and being more economical. The author concluded with some remarks on the necessity for keeping the Goliaths on the rails, the ballasting of cranes, the shape of contractors' waggons, the most economical way of supplying materials to the works, &c., and after a discussion the usual vote of thanks was accorded.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE closing meeting of the present session of the Institute was held on Monday, the President, Mr. John Whitehead, in the chair. Several donations to the premises improvement fund and to the library were announced by the Secretary; and the President, in proposing a vote of thanks to the donors, referred especially to a monograph on Melrose Abbey, presented by the author, Mr. Fredk. Pinches, who won the Institute silver medal to be presented that evening with some of the drawings by which it is illustrated. The following gentlemen were balloted for and elected as members:—As Fellows: John James Stevenson, M.A., and Andrew Heiton. As Honorary Associates: James Lattey, Edwin Freshfield, M.A., F.S.A., Edward Stanley Roscoe, Morgan Howard, Q.C. (Recorder of Guildford), Rt. Hon. William Henry Smith, M.P. (First Lord of the Admiralty), and Albert George Sandeman.

PRESENTATION OF THE ROYAL GOLD MEDAL.

The Hon. SECRETARY announced that the Marquis de Vogüé, to whom the Royal gold medal is given this year, was unfortunately unable to be present owing to an important family circumstance, but that he had requested M. le Comte de Florian, secretary of the French Embassy, to receive the medal on his behalf.

The PRESIDENT, requesting the Count of Florian to approach the chair, and addressing him, said it was his high privilege to present him, on behalf of the Marquis de Vogüé, with the gold medal annually given by the Queen. The Council, on the motion of Mr. James Fergusson (whose absence that evening he much regretted), had recommended that the medal for the current year should be awarded to the Marquis de Vogüé; this was unanimously adopted by the Council, and also by the general body of members, and had been approved by the Queen. He proceeded to sketch the salient points in the career of M. de Vogüé, stating that his first efforts to explore ancient countries once renowned, but now slightly peopled and little known, were made while he was attached to the French Embassy at St. Petersburg, from 1819 to 1851, when he published some essays on the Ancient Art of Russia. In 1853-54 he visited Greece, Syria, and Egypt, the result of which may be seen in his well-known work on the Churches of the Holy Land, as well as in other minor works on the "Semitic Characters." At the

close of 1861, M. de Vogüé started to join M. Waddington, his great friend, and now one of the most distinguished ministers in the French Cabinet, who had, six months before, explored parts of Central Syria and made important discoveries. Together, during the whole of the year 1862, these travellers visited Central Syria, and soon after their return M. de Vogüé published his book on the Temple of Jerusalem, and commenced the publication, in parts, of "La Syrie Centrale,"—a series of accurate architectural drawings of numerous cities dotting a vast plain, and presenting a chain of monuments illustrative of Early Christian construction between the 4th and 7th centuries of our era. In that exploration M. Waddington, who, members were proud to remember, though a French minister has carried away honours from our universities, and is the son of an Englishman, devoted himself to the study and collection of inscriptions, and M. de Vogüé to drawing and architectural research. Sketches for the plates illustrating "La Syrie Centrale" were prepared by the Marquis, assisted by Mr. E. Duthoit, an architect of distinction; and when circumstances permitted, these illustrations were completed on the spot. This was particularly the case for the drawings of Jerusalem, and for many of those of Djebel Semán. Every detail was measured and figured with the utmost minuteness, and photography was sometimes employed to aid the explorers. But apart from M. de Vogüé's literary and artistic fame, he is familiar to English architects as the bearer of a name associated with the Hôtel de Vogüé—a masterpiece of the Renaissance, situated at Dijon, and not the least instructive of those historical monuments for the conservation of which the French have passed statutory enactments enforced to the advantage of all architectural tradition, and to the special honour of their country. That celebrated residence, inhabited by the father of the Marquis of whom he was speaking, probably fostered a taste for the Arts which, hereditarily transmitted, led the young Melchior de Vogüé to seek occupation for his leisure in lands where the earlier records of history lay, like an open book, to be read by any one who could decipher and understand. The character of these archaeological researches was not ignored by the French Government. In 1871 M. de Vogüé was nominated Ambassador at Constantinople, where he remained until 1875, and where, while devoting himself to official duty, he could still continue his early study of Oriental art—study that a few years before had obtained for him the envied distinction of membership of the Academy of "Inscriptions and Belles-Lettres." In conclusion, the President presented the medal, remarking that upon the brilliant roll of gold medallists, not the least distinguished were the compatriots of M. de Vogüé—MM. Hittorf, Texier, Joseph L. Duc, Lesueur, and Viollet-le-Duc, of whom the first three were, unhappily, dead.

Professor DONALDSON said he wished to add a few words to the address in which their president had pointed out the claims to the esteem of architects possessed by the Marquis de Vogüé as a real archaeologist, and architectural student and author. He wished to allude to the new beauties which archaeological research was able to produce on the buildings of modern times. In Central Syria he had explored and made known to them architecture of a most interesting kind. It was a sterile country, utterly without trees of any large size, and so construction in wood was impossible, and all building must be accomplished in stone. Their temples, houses, and all dwellings were of stone to the minutest point of detail; even the staircases were solidly built in this material, and were made an external feature. These buildings were decorated in a more delicate and purer style of tracé architecture than the temples of the Antonines at Baalbek and Elmirá; but whereas the latter temples were well known, the world was not aware of the existence of these more interesting structures—echoes of a more refined Greek taste—until MM. de Vogüé and Waddington published their great work. Near Aleppo, again, the travellers made further discoveries, and all these had been published in very admirably executed plan, elevation, and section. The drawings were beautifully finished, and had been engraved almost as carefully as it would be possible to do in this country. He wished some of the younger members of the profession would explore the new world of taste and refinement

in architecture which had been opened up to them in his works. He trusted he would be pardoned for mentioning that he had in 1847, when he was secretary of the Institute, the honour of proposing that the Queen be applied to to grant a gold medal. The suggestion was opposed at the time, but he was glad it was adopted, and that it was acceded to by her Majesty. He was further glad to know that it was not confined to distinguished Englishmen alone, but was awarded to the men of all nations, and aided in building all together in the brotherhood of art. The Institute had carried that idea out well; for every third year it was its practice to look abroad and give it to some eminent archaeologist or architect on the Continent. He heartily concurred in the present award to one who had done honour to his country and to his art.

Mr. CHARLES BARRY added a few words expressing his approval of the award, and intimating that other names of distinguished Continental savants were suggested to the council, but M. de Vogüé was unanimously approved.

M. le Comte de FLOURIANS responded (in English) on behalf of the Marquis de Vogüé, thanking the members for the honour they had conferred on him and on his country by the presentation of the medal, the highest honour such a scientific and learned man could aim at. He also gracefully acknowledged the references to M. Waddington's researches. Their explorations of the remains of hygone eras had probably convinced the Marquis de Vogüé and his friend that nothing was lasting in this world but what was good, righteous, and fine. He would again join with the Marquis in thanking them for the honour shown in conferring on him this much-valued distinction.

THE PRESENTATION OF PRIZES.

The PRESIDENT then distributed the medals, prizes, and certificates for the past session as follows, accompanying each with appropriate remarks:—Pugin Travelling Studentship (certificate and £40 to be hereafter presented), awarded to W. J. N. Millard; honourable mention, Frederick Hemmings. The Soane Medallion (with £50 to be afterwards presented under the usual conditions), William R. Lethaby. The Tite Prize (£30 with certificate), E. Sayer; medal of merit, Herbert Alexander Pelly; and honourable mention, Frederic Edwards. The Grissel Gold Medal, G. H. Blagrove. The Institute Silver Medal (with five guineas), Frederick Pinches; honourable mention, Sydney Vacher. The last-named recipient was unable to be present as he is now studying at Florence.

THE ARCHITECTURAL EXAMINATION.

The SECRETARY read the report of the examiners which had been presented that day. In the preliminary class, out of nine competitors four had passed, namely: Wm. Balcombe, of Brighton; E. F. H. Nicholson, Reading; Henry Rennie, Sunderland; and Walter Scott, Holloway. Eight entered for the proficiency class, of whom seven passed, but of these only two passed in both sections, three passed in that of art alone, and two in that of science. Their names were W. Llewellyn Harford, of Manchester; and Bruce G. Capel, who passed in both science and art, and the council recommended the latter for the Ashpitel prize. F. T. Goldsmith, of Newport, Mon.; F. G. Summers, of Nottingham; and W. Jacques, Fenchurch-street, City, passed in art; and T. W. Moss, of Hornsey; and H. G. McLachlan, of South Kensington, passed in science. In the preliminary class one gentleman's examination was so creditable that the council recommended the Institute to award him a prize of some books—this was Walter Scott. It was noticeable, the Secretary added, that both the prize-takers were educated in one office, that of Mr. Rowland Plumb.

THE NEW PREMISES SCHEME.

The PRESIDENT said that as this was the last meeting of the session, he desired to say a few words with reference to the premises improvement scheme. He trusted that at their next meeting in November the members would then assemble in them, enlarged and improved in the manner for which authority was given the council at the general meeting in May. Great labour had been bestowed by the council in the endeavour to make the improvements as perfect as possible, and the suggestions thrown out at

the general meeting had been borne in mind, especial thought being bestowed on the ventilation and warming of the room in which they were sitting. He believed the problems had been solved in a satisfactory manner, and a contract had been entered into, and a new lease arranged with the Architectural Union Company. The contract rather exceeded the sum named at the general meeting, namely £2,000, in fact another £600 or £700 would be needed. As full authority had been given to the council the contract had been entered into, and the matter was now merely mentioned to the members; but he urged the necessity for increased subscriptions. When the improvement fund was started they did not know what was proposed, and now that this was decided upon he trusted many would follow the example set by some who had doubted their subscriptions, and that those who had not given would do so.

Mr. CHAS. BARRY mentioned that two schemes were brought before the council, one involving an expenditure of from £5,000 to £6,000, and that now adopted, and followed up the appeal of the President for further subscriptions.

This concluded the business of the session.

SOME EXPERIENCES OF SEWAGE EFFLUENTS AND BURNING SLUDGE INTO CEMENT.*

DURING the past year it has been my duty to watch the process for purifying the sewage now being carried out at Burnley, in Lancashire.

In a paper which was read by Mr. Richards last year at this Conference, the method of dealing with water-carried sewage by General Scott's system of precipitation by lime, and utilisation of the sludge for cement, was described. This process has now been carried on for nearly eighteen months. The sewage is purified, and the effluent—samples of which have been submitted for analysis to two of the highest chemical authorities—is certified by one to be fit to be poured into a stream of ten times its volume, by the other to be fit to be poured into a stream, having a velocity of at least three miles an hour, of fifty times its volume. Both these conditions are fulfilled at Burnley. This effluent could be further purified at a comparatively trifling cost to towns by intermittent downward filtration, requiring only one-sixth of the land, which, according to the Rivers Pollution Commissioners' 4th Report, unprecipitated sewage requires. The Corporation of Burnley have not required that this should be done, but the injunction against the town has been suspended. In the case of Burnley, the stream into which the effluent is poured varies very much, according to the weather. In wet weather I have seen the Pendle water, as the stream is called, rise several feet in as many hours. I abstain from giving the many analyses I have made of the effluent water, and comparing it to the averages given by the Rivers Pollution Commissioners. A fair average could only be obtained, in my opinion, after daily observations, extending over a year. The rainfall at Burnley is exceptionally high, and the neighbouring hill, the Pendle, collects and pours the rain into the Pendle water. The Pendle water itself rises not far from the small, old town of Colne, and receives the raw sewage as it flows by. It then flows past the townships of Nelson and the village of Barrowford, on the west of the village of Brierfield, from all of which places it receives more raw sewage before it reaches Burnley. A scheme is now under consideration for the federation of these places, in order to bring their sewage to the Burnley sewage works for purification. Should this scheme be successfully carried out, the Pendle water will certainly be one of the cleanest streams in Lancashire. I have several times noticed that the stream is very much dirtier than the effluent poured into it from the Burnley sewage works.

Portland cement is manufactured from chalk or limestone and clay. The component parts of these materials varies very slightly and, therefore, the manufacture is nearly constant. The average analysis of five large manufactories gives the following results, viz.:—Lime, 56·21 per cent.; silica, 24·44 per cent.; iron, alumina, 12·1 per cent. The manufacture of Portland cement from sewage is much more precarious. Sewage, according to my experience, varies in every

place, and during every hour, and consequently has to be carefully watched in order that the requisite quantity of milk of lime may be added. At Burnley, on certain days, large quantities of dye water come down, on other days butchers' refuse, and once or twice we have observed the sewers full of coal-tar and oily refuse; all these facts have to be carefully observed, and only after careful experiments can the quantity of lime necessary to precipitate the sewage be determined. The resultant sludge at Burnley on an average only contains 46 to 50 per cent. of lime, and, therefore, before it is fit to be burnt into Portland cement clinker, more lime has to be added. This is done after the supernatant water has been run off the sludge deposited in the tanks. The sludge has afterwards to be passed through a pug-mill in order that a uniform compound may be obtained. At Birmingham, where Portland cement was also made, the sewage is so capricious that a uniform manufacture could not be guaranteed. This is accounted for by the fact that at certain times very large quantities of acid from the hardware manufactories of the town are poured into the sewers. At Portsmouth, where I have studied the sewage, which is wholly water-closet and house drainage, there is little or nothing to interfere with the manufacture of a high class Portland cement; I believe the same remark would apply to the Lower Thames Valley sewage. The sewage requires only a small quantity of lime to dehydrate it; 16 grains of quick lime per gallon is ample. The sludge I have found generally contains from 53 to 60 per cent. of lime, and, therefore, no fresh lime would have to be added. The fact that at Portsmouth the storm water is partially kept out of the sewers is also greatly in favour of the manufacture of good cement. And in places where the separate system is in force, and where the proportion of water-closets is large, it would be, perhaps, worth while to allow the finely suspended organic matter to subside before lining, and to treat the organic matter described in General Scott's patent.

The sludge resulting from limed sewage may also be burned at a lower temperature than that necessary to produce Portland clinker, and be used to participate the sewage. After this has been done several times, the lime becomes rich in phosphates, and may be profitably sold as a first-class agricultural lime. The cement now being made at Burnley is much improved in quality since the manufacture began, and much has been sold. The latest tests give excellent results. Mr. Deacon, borough engineer of Liverpool, reports the tensile strain of 695lbs. on the 1½ in. square, and that the cement passed through a sieve of 50 meshes to the inch, leaving only 7 per cent. of residue. The latest test at Burnley gives 698lbs. A portion of a sea-wall at Portsmouth has been built with it, and it has stood this test remarkably well. Much has been learned since the process was first started at Burnley, and it may be fairly expected that towns will obtain purification, and at the same time will recover the greater part of the cost of so doing, by adopting this process.

CHIPS.

At the Metropolitan Board of Works, on Friday, an application of the Greenwich District Board for permission to borrow £2,460 to defray cost of erecting stables, cart lodges, and disinfecting apparatus on their premises at Deptford, was granted to the extent of £2,400, and permission was also given to the vestry of Shoreditch to borrow £10,000 for the purposes of the Sun-street improvement. It was proposed to contribute a sum not exceeding £2,000, being one-half the estimated cost of an improvement proposed by the vestry of Shoreditch by the opening up of Harwar-street (late Thomas-street).

At the meeting of the West Ham Local Board, held last week, Mr. Angell, the surveyor, submitted plans for the carrying out of the first section of a scheme of surface drainage for the parish; this would extend from the "Princess Alice" at Upton, along the Romford-road and Stratford High-street to Bow-bridge, and its estimated cost would be £9,000. Two other sections will hereafter be prepared, the total estimated cost being £25,000. The scheme was adopted, and the surveyor was requested to obtain tenders for the execution of the work.

The *Lealtad*, a Madrid newspaper, reports that the Alhambra is in imminent danger of destruction. It states that during the last days of May the hill upon which the choicest relic of Moorish art stands shows signs of an approaching landslide, and since then the appearances of collapse on a colossal scale have increased.

OUR LITHOGRAPHIC ILLUSTRATIONS.

ST. PETER'S CHURCH, BOURNEMOUTH.

ST. PETER'S CHURCH, Bournemouth, has been very many years in course of building. There was a mean building in the first instance, to which an aisle of not very much better character was added on the south side, and the church was in this condition when Mr. Street began the reconstruction of it. A north aisle and arcade were first of all erected, then the old south arcade was taken down and rebuilt, and a clerestory added to the nave. Then a chancel of consistent size and character, with eastern transepts, chancel aisles, and upper and lower vestries, were erected, and the church being still not large enough for the increasing congregation, western transepts were added, and a western tower. The church is now, therefore, one of unusual scale and variety of character. It owes a great deal, no doubt, to the fact that its scheme has been developed by degrees and to meet requirements as they arose. The spire is now in course of erection by Messrs. Wall and Hook, the tower having been built a few years back by Messrs. Dove Brothers. The church is about 170ft. long inside: the chancel being 50ft., and the nave, exclusive of the tower, 98ft. The width of the nave is 53ft., the height of the tower 98ft. and the tower and spire, when finished, 200ft. There is an elaborate south porch. The tower and chancel have groined roofs, and the decorating in the way of painting on the walls and the stained glass in the windows are very elaborate. The churchyard crypt is an important feature in the churchyard, being of large size, and having on its base the crucifixion and three other sculptured subjects. The churchyard of this church is probably the most beautifully kept and arranged churchyard in England. The extensive value of the works which have been done in this and other dependent churches in Bournemouth is owing entirely to the zeal and energy of the vicar, the Rev. A. M. Brunett, who has seen the place increase from a village to a town of some importance during his incumbency.

"THE SCHOOLS," OXFORD.—INTERIOR OF GREAT HALL.

THE illustration shows Mr. T. G. Jackson's design for the great hall fronting High-street, which forms the vestibule and principal waiting-room of the building. The hall is to be panelled and ceiled and roofed with oak, and a stone arched gallery springing from stone brackets runs along the inner wall to afford a passage for examiners on the first floor. On the ground floor the hall opens by three large elliptical arches into the main corridor, beyond which are the *ried rooe schools*, ranged round the inner quadrangle. The building is now well advanced, part being roofed in, and the rest raised to about

two-thirds of its height. We illustrated Mr. Jackson's design by perspective of High-street front and bird's-eye view of quadrangle, together with ground and first floor plans, on December 22, 1876—p. 622, vol. XXXI.

ROYAL ALBERT ASYLUM, LANCASTER.

We gave a single-page illustration of this building in the BUILDING NEWS of Oct. 9, 1874, and a full description at the same time. The present illustration is, however, a much superior one, and is, moreover, accompanied by a complete plan. The building, which will accommodate 600 inmates, cost £63,742. The exterior is built of a local light-coloured freestone, relieved with red stone. The roof are covered with Coniston green slates. Messrs. Paley and Austin, of Lancaster, were the architects, and Mr. John Combe the clerk of works.

END OF HALL FOR C. NOSOTTI, ESQ.

The illustration shows design for end of hall, and includes gallery, staircase, &c. The wood-work to be in oak (stained), panels in frieze, and ceiling to be in carton pierre and gilt; tapestry under side arches, and panel between windows; walls above dado in plain colour. It was designed for C. Nosotti, Esq., of Oxford-street, W., by Mr. C. Gill, and exhibited in the present R.A. Exhibition.

THE BELFRY, CHRIST CHURCH, OXFORD.

The drawing shows the new stonework of the tower as recently completed. The upper part of the belfry it is intended to have carried out at a future time. It would be of open work constructed with timber, covered with lead or copper, and is an essential part of the design. The four turrets need this central feature, and indeed without it the design is wholly incomplete. Such a finish is much needed in order that the belfry should compose well with the lead dome of the entrance gateway, and with the spire of the cathedral. It is to be hoped that this, so essential a completion to the design of the belfry, may be added at no distant time. The stonework of the quadrangle has been restored. It was in a state of much decay. The walls were finished with a balustrade of Georgian date. It was so decayed, and, indeed, in a dangerous state, and would have had to have been reproduced in new stone. Instead of this a new parapet with battlements has been put, as being more in accordance with the work of the original building. The work has been carried out under the direction of Messrs. Bodley and Garner, of 14, South-square, Gray's-inn; Mr. Fitzwilliam acting as clerk of works.

HOUSES IN CADOGAN-SQUARE, CHELSEA.

MR. R. NORMAN SHAW's principal picture at the Royal Academy last year is that which we have reproduced among our illustrations to-day. The subject is one of the author's most happy designs, in the Free Classic sort of style which, against all comers, he has continued to uphold as his own, and it represents the houses in Cadogan-square now nearly completed. Mr. Shaw has sent us no particulars, treating the matter as one of no more interest than ordinary town houses in red brick and tile.

MANSION FOR RT. HON. SIR ROBERT COLLIER, CHELSEA, S.W.

THIS house is built on the Thames Embankment facing Battersea Park, on a site reclaimed from the Thames by the Metropolitan Board of Works. It has a frontage of 60ft., and a depth of 112ft. The accommodation of the second and first floor is shown on the plans; on the second, third, and 4th floors are nine bedrooms and dressing-rooms, two nurseries and lumber-rooms. In the basement are the usual offices, including kitchen, scullery, larders, butler's pantry and bedroom, men-servants' rooms, servants' hall, house-keeper's-room, store-room, wine-cellar, &c. The house is built in brick, with picked London stocks for facing; the moulded quoins and heads to windows being in red brick; the cornices, tympana of gables, and other decorative work are in terra-cotta, being supplied by the Architectural Terra-Cotta Company, Maplin-street, E., the whole of the work having been specially made from the architect's designs. The work has been carried out by Messrs. Kirk and Randall, of Woolwich, from the designs and under the superintendence of Mr. R. Phené Spiers, F.R.I.B.A., architect, of Arthur-chambers, Regent-street. Mr. Gale was the clerk of works. A water-colour view of the house is at the Royal Academy this year.

EDINBURGH UNIVERSITY.

OUR illustration of the new buildings for the Edinburgh University, which we publish to-day, is taken from the drawing exhibited this year at the Exhibition of the R.S.A., excepting the plan, which we have included in the plate. Mr. Robert Anderson, of Edinburgh, is the architect, and he has chosen the Italian style of the Cinque Cento period, which was developed in the end of the fifteenth and beginning of the sixteenth centuries. The principal entrance is through the archway, under the central projecting bay of the main front, to the N.W. of which is placed the great campanile, with its pyramidal roof. A colossal statue surmounts its apex, at a height of 250ft. from the ground. The common hall is semicircular on plan, and has its façade diversified at regular intervals with massive buttresses, in which niches are cleverly arranged for statuary. Considerable skill has been shown by allowing the character of the building to express itself in the treatment of the several frontages, to each of which a picturesque variety has been secured, without any sacrifice of a general balance of parts. The furnace-shaft, which rises in the anatomical court from the heating-furnaces, has been architecturally treated. The general distinction of the several departments is clearly shown by the plan which we give to scale.

THE COUNCIL-CHAMBER, WAKEFIELD TOWN-HALL. THIS illustration represents the interior of the council chamber of the Wakefield Town-hall, of which Mr. T. E. Collentt is the architect. It is proposed to cover the lower portion of the walls as shown on the drawing, with an American walnut dado, slightly polished, and above that have raised plaster decorations, adapted from some fine old leather raised work in the possession of the architect. At the lower end of the room is the lobby of the principal entrance, and space for reporters, the gallery for the public being above. The chairs and tables are to be in American walnut also. The painted panel to fireplace was suggested by Mr. T. W. Linton, and is taken from "Henry VI." We may here state, with reference to the paragraph which appeared last week on p. 706, that the architect informs us that there has been no estimate for fittings, &c., and consequently the amount has not been exceeded as was stated.

DESIGNS FOR AIR-PUMP VENTILATORS.

THE air-pump ventilator, manufactured by Messrs. Robert Boyle and Sons, of Glasgow, is well-known to most of our readers. Its intrinsic merits have been described by us some time ago, and its adoption by the late Sir Gilbert Scott, Mr. Arthur Cates, and other leading architects, has in every case been attended with satisfactory results. Satisfied with the principle of their ventilator, Messrs. Boyle and Son have evidently recognised the fact that in the majority of cases the adoption of such contrivances has almost invariably marred the exterior of the buildings to which they have been fixed. We are but too familiar with the hideous additions to roof exteriors, added without consulting architects, under the plea of ventilation, and we think the idea of Messrs. Boyle and Son in publishing the sheet of designs which we publish to-day was a good one. The sketches prepared by Mr. Maurice B. Adams show at any rate that henceforth pure air may be enjoyed without offence to art—rather in fact furnishing a justification for the addition by the architect or builder of an ornamental feature to his building. At the same time economy has been studied as in the first design shown, which is meant to bring the ventilator within the reach of all, and is, so the makers inform us, twenty per cent. cheaper than any similar contrivance. The other sketches are of course simply suggestive, with the exception of the centre illustration, which represents the manner in which Messrs. Boyle and Sons' ventilator has been adopted at Christ Church, Lambeth. It may be interesting here to append the result of its use in that building. Some time since Mr. H. J. Paull, the architect, the builders, and others interested, tested the ventilator during the service; when it was found to be extracting air at the rate of 8,000 cubic feet per minute, or 480,000 cubic feet per hour. There was but a moderate breeze at the time. During the whole time the experiment lasted there was not the slightest draught experienced, nor was there at any of the other experiments, of which there were several. The Rev. Newman Hall, in a letter to a friend, referring to the ventilation of the church, says, "I consider our ventilators very successful."

OUR COMMONPLACE COLUMN.

HOSPITAL

FROM *hospitia*, a term also applied to the mediaeval leper hospital. We confine our attention here to hospitals for the reception and treatment of the sick and hurt, sometimes called infirmaries. Of the London hospitals, St. Thomas's, founded in 1553, St. Bartholomew, in 1546, and Bethlehem, in 1547, are the oldest. As a fair example of a town hospital, the Middlesex hospital, in the parish of Marylebone, may be cited. It is disposed in the form of a letter H, and comprises 310 beds, of which 120 are for medical, and 190 for surgical cases. Three wards are set apart for patients affected with cancer. There are resident house surgeons, an apothecary, and a chaplain. In the planning of hospitals, the first essential is the separation of the administrative portion from the hospital proper. The administration offices should be central so as to facilitate service to the wards, and in the best modern hospitals those offices are placed in a block arranged upon a central axis, the waiting and surgeons' rooms being in front. There are two well-known principles of arrangement, namely, the "pavilion" and the "barrack" systems. The first-named plan is that now generally considered the best: the wards form self-contained separated blocks, placed in parallel rows, and connected by a central or end corridor. It is best to place the pavilions about 100ft. apart, in parallel lines with their axes nearly north and south, connected by long corridors. In the centre the administrative building should be placed, and this has sometimes detached blocks or pavilions for private patients on each side. The acute cases should be separated from the chronic and convalescent ones, as patients suffering from acute fever require a lower temperature and less light than those with chronic rheumatism or suffering from debility. Acute cases may be estimated at 25 per cent. of the total number. The wards may be 96ft. long, by 26ft. wide, and contain 24 beds—12 on each side. Windows are placed opposite to promote cross-ventilation. In good wards 100ft. of floor-space to each patient is necessary, the beds having 8ft. of wall-space. The smaller wards for separate cases may be attached at one end of the longer ward on one side of corridor, while on the other side may be placed the nurse's room, dining-room, and kitchen. At the other end of ward the bath-room and water-closets should be attached with an isolated lobby. In a work published in America, entitled "Five Essays Relating to the Construction, Organisation, and Management of Hospitals, Contributed by some of the leading Physicians for the use of the Johns Hopkins Hospital of Baltimore," reviewed in our pages (see 2nd Vol. of BUILDING NEWS for 1876, p. 361, *et seq.*), several suggestions are embodied. Some authorities recommend the temporary or tent hospital principle favourable for infectious cases, but the buildings upon this plan cover a large area and are only suitable for military uses where land can be obtained cheap. Others prefer one-story wards for 20 to 30 patients, so that ridge ventilation may be secured. These may be square-shaped, 56ft. by 43ft. for 23 beds, with a central chimney-stack and stoves on two sides, a similar plan being adopted at the Massachusetts General Hospital. A bay-like projection on the south side affords a useful recess in cold weather. These blocks are strung together by a transverse corridor at their north end, on the other side of which are the dining-rooms. No doubt where land is unlimited the one-story pavilion is the best, but the two-story pavilions are more economical in construction. Another suggested plan for one-story pavilions is to arrange them in parallel rows, 65ft. apart, with the administration block between. Each ward is made 90ft. by 30ft., with service blocks 50ft. long by the same width (see BUILDING NEWS for 1876, Vol. XXXI., page 563). Generally 20 to 24 patients in a ward are considered sufficient.

The space allowed by the Poor Law Board for civil and military hospitals is 850 to 1,200 cubic feet per man, but for new hospitals 1,300ft. per patient, and 1,500ft. in acute cases is recommended.

The octagon plan of ward has been strongly recommended by some authorities, as it turns more flanks to the air and sun than any other; the corridors should always be placed on the north side of wards. For the suggested plan of the John Hopkins Hospital we refer our readers to an article and block plan that ap-

peared in the BUILDING NEWS, Vol. XXXI., page 463. The block arrangement consists of a U-shaped connecting corridor, upon each arm being strung the common and service wards; these are placed transversely, their axes being north and south. At the ends of the long corridors are two isolating wards for dangerous patients, for 20 beds each. The administration building is attached to the front corridor, and is isolated at the sides, while two short advancing wings in front are devoted to the male and female patients' pay wards. The offices and house dispensary are in the centre behind the front corridors; the operating theatre, kitchen, and laundry building are detached buildings on the north side, the kitchen and laundry being approached at the end of the front corridor. Isolated tents are placed along the south wing, though completely outside. For details and plans we refer the reader to back volumes of the BUILDING NEWS, also to the work above quoted, and to the Local Board Regulations of Hospitals.

The following contribution is sent by "C. F. W.":—

"Hospitals," says a writer in Weale's "Dictionary of Architecture," &c., "were originally designed for the relief of poor and impotent persons, and the entertainment of travellers upon the road, particularly of pilgrims, and therefore they were generally built upon the roadside. There existed in England above 358 of these houses of relief." Under the title of "Hotel Dieu," M. Viollet-le-Duc gives an interesting and critical article on hospitals. He remarks that there is nothing to prove that certain houses were set apart by the ancients for the relief of the sick. At Athens wounded soldiers were provided for at the expense of the republic, but this was probably nothing more than a pension, and no other Greek town appears to have had it. The Romans had set apart places in the country for invalided men and horses; no authority, however, mentions the existence of a building devoted solely to the wounded and indigent sick.

St. Jerome the First speaks of a certain very rich Roman lady named Fabiola, who founded (c. 380 A.D.) an hospital for the sick, who until that time lay neglected in the streets and public places.

At the beginning of the Middle Ages, in the towns of Italy, France, and Germany several establishments were formed for taking care of and harbouring the sick, travellers, and the poor.

During the 11th, 12th, and 13th centuries an incredible number of hospitals were founded. Almost all the abbays had a hospital within their precincts, in addition to a large number of lazar houses established outside of towns and cities. It has been computed that there were no less than 19,000 lazarettes in France, Germany, England, Italy, Spain, Brabant, Switzerland, Hungary, Poland, Bohemia, and Denmark.

In concluding the article, our learned author says that the buildings are of a monumental aspect, without being rich. The patients have space, air, and light. They were separated from one another, as may be proved; their individuality was respected. It is doubtful whether one spacious room for a number of patients is advantageous. Often the suffering of each patient is increased by the sight of that of his neighbour. Without claiming that the cellular system was frequently adopted in the Middle Ages, it is certain from a moral point of view that it presents an advantage. We believe that our hospitals owe their origin to a sentiment of very noble charity which was present in the hearts of their constructors and founders.

Mr. Dollman, in his preface to "Domestic Architecture," makes some valuable remarks. "In examining the plans of various buildings illustrated in the present work, the component parts that appertain to all of them will be found to consist of an audit room, occasionally with a muniment room adjoining a suite of apartments, more or less extended for the master or chaplain, an infirmary for the sick, and, lastly, a chapel, which, with becoming significance, was always more ornamental in character than the other buildings. The first, and that perhaps of which the characteristics are the most definite, is to be found in those instances where the abodes of the inmates were all under one spacious roof, the area being subdivided into small dwelling-rooms or dormitories. The hall communicated directly with the chapel beyond, from which it was only separated by an open screen, thereby affording

an opportunity to the sick and aged of hearing the recital of the Church's Service, from which, supposing the chapel to be a distinct building, they would otherwise have been debarred; as examples, we may mention the Bede Houses, at Stamford and Higham Ferrars, and St. Mary's Hospital, Chichester. The second kind is where the dwelling-rooms for the inmates were, as before, under one roof, but the chapel, though undoubtedly contiguous, was a distinct building entered from without, as at St. John's Hospital, Northampton. A third variation is where the abodes of the inmates formed one continuous suite of buildings, sometimes within a quadrangle, but not, like the foregoing, included under one roof, the church or chapel being altogether distinct, but connected with the hospital buildings by an ambulatory or cloister, or by a short covered way only, as at St. Cross, near Winchester; Ewelme, Oxon; Cobham, Kent. A fourth mode of arrangement, differing somewhat from the foregoing, is to be met with in the case of Ford's Hospital, Coventry, where the plan consists of a central open court on each side of which are almoners' abodes, at one end of the quadrangle the common hall of the hospital, and facing it at the other end the chapel.

It is worthy of note that with the exception of St. Mary's, at Chichester, the chapel of which is of Geometrical Middle Pointed character, and the church of St. Cross, which is chiefly Transition Norman, none of the examples are anterior in date to the third Pointed or Perpendicular Period; the domestic portion of the hospital, if they existed in the same style, have been entirely destroyed.

We will conclude this article by quoting, or rather condensing some practical remarks from Dr. Oppert's volume on Hospitals.

Formerly large hospitals were founded on the principle that by increasing the number of patients who could be accommodated, the benefit conferred on the sick poor of the community was also increased; but in recent times contrary views are strongly maintained. Large hospitals are described as unhealthy and dangerous to those who seek recovery of health in them. It is stated that a great many sick people living together under one roof engender certain diseases which are well known under the term of hospital diseases. In selecting a site the following are the chief points to be observed:—1, the general healthiness of the locality; 2, the easy accessibility for patients and others who visit the hospital; 3, convenient position for clinical instruction; 4, cost of erection and maintenance.

If one side looks south-east, the other faces north-west; and this seems to be the best position (except in cases of wards for diseases of the eye, where the patients require as little light as possible). Their wards may be northwards, but all other patients want light and sunshine.

Whatever may be the style of architecture—Gothic, Italian, or mixed—I should not object to a fine clock-tower and an ample porch; the chimneys need not look ugly, and narrow entrance doors can be avoided.

The architect ought to dispense with arched windows. The material of which the walls are built should be good bricks. If the walls are to be plastered, it is better to leave that until about a year after the completion of the building, for the wall to get thoroughly dry; and it is better to plaster or cement them first inside and then outside, because if the outside is left open to the drying action of the atmosphere the inside walls retain less humidity.

The plan of a circular building is as bad as the closed quadrangular. A better one is where one side of the court is open. There the air is less stagnant, because the wind can sweep through from one direction. The wings and centre may form one long block; this is better still. They may assume the shape of the letter H (Middlesex Hospital), where the administration part is in the centre, having the wards for males on one side and those for females on the other.

The hospital may be built in such shape that the letter L (Sheffield Royal Free) or T (St. Mary's, Oxford) is formed, and in both cases staircases may break the communication of the different parts from the whole.

Several plans may be combined; but in no case can the free circulation of air, which is necessary to keep the hospital healthy, be more favoured than in the Pavilion plan. Here each block is a hospital by itself, and yet is connected with the others.

As to the relative position of the different

parts of the hospital, the following should be observed:—

First the offices for administration, the sleeping-rooms of the officials, medical men, nurses, &c., must be separated as much as possible from the wards.

Secondly, the kitchen must not be in the basement or ground-floor but quite separate, connected with the main building by a corridor.

The engine-room should be in a separate shed; washhouse and deadhouse should be detached.

Male and female patients should be accommodated in separate parts of the hospital divided by the principal yard; and they should not use the same day-room.

There should not be more than two floors in a building intended for a hospital. It will be generally found that the best plan is to give additional height to those parts of the building where the offices are situated, and to have fewer floors in that portion devoted to clinical patients.

METROPOLITAN RAILWAY EXTENSIONS.

AN important extension of the Metropolitan and St. John's Wood Railway to Harrow is now in course of construction. It commences, according to the *Engineer*, by a junction with the existing tunnel under the Finchley-road, about 500 yards north of the Swiss Cottage Station. The present tunnel will be lengthened about 80 yards, and at its mouth a station will be erected, opening on to the Finchley-road. Half a mile further on the line passes under West End-lane, where there is to be another station, which is already in an advanced state. It next crosses over the Hampstead branch of the London and North-Western Railway, a work of considerable difficulty, as that line is itself formed on an embankment about 25ft. high, and the foundations for the new bridge had to be carried down through this embankment to the solid ground beneath. A second opening is also provided so as to permit of the widening of the London and North-Western to four lines of rails at a future period. For the next quarter of a mile the new line is carried on a viaduct consisting in the main of semicircular brick arches of about 30ft. span, but having also four larger openings at the points where it crosses the Iverson-road, the Loveridge-road, and the Edgware and Christ Church-roads. The two first-named roads are crossed by noble brick arches built in ribs of blue Staffordshire bricks set in cement, the spans on the square being respectively 104ft. and 84ft., and the heights from the roadway to the under side of the arch 28ft. and 23ft. The Edgware and Christ Church-roads are also crossed by large arched bridges with spans of 80ft. and 70ft., and headways of 20ft. and 17ft. respectively, but in these cases the material employed is cast-iron, as the headway at the disposal of the engineer did not admit of brick arches. It is proposed to place a third station at the Edgware-road, and every exertion is being made by the company to have this, as well as the two other stations before mentioned, sufficiently completed to enable them to open the line up to this point in time for the show of the Royal Agricultural Society of England, which is to be held in the immediate neighbourhood.

After crossing the Edgware-road the line enters upon what is at present a more rural district, although the land from this point to the river Brent, near Kingsbury-bridge, is rapidly being laid out for building, and will soon constitute another suburb of the metropolis. A considerable extent of land has been purchased by the railway company in this district, part of which will be used for the erection of locomotive shops, of which the company stand in great need, and the rest will be sold off for building purposes. The United Land Company has also just laid out a considerable estate for building, and the other landowners are more or less following their example. Stations will be provided at once at Walm-lane and the village of Neasdon, and land will be reserved for the erection of another and intermediate station when the growing traffic requires it. The works on this section are in a forward state. On the remaining portion of the line, from Kingsbury to Harrow, the works are only just commenced, but as the greatest part of the land has now been arranged for, they will soon make good progress. The com-

pany's station at Harrow will be a mile nearer to the town than the present one on the London and North-Western Railway, and at a much higher level, which will be a great boon to the inhabitants. A somewhat peculiar system of construction is adopted at Iverson-road. The bridge, instead of being built on the skew system, consists of a series of vousoirs ribs stepped back behind each other on one side and advanced on the other. The method of construction is simpler than that usually adopted, and no doubt equally efficient. Mr. Charles Liddell, Abingdon-street, Westminster, is the engineer, and Mr. Joseph Firbank, the contractor for the works.

CHEAP LOCKS.

WHETHER or not the Americans are beating our own lockmakers, as some have recently thought, it is evident they are alive to the defects of the ordinary common lock and its appendages, and not backward in suggestions for its improvement. The *American Builder* says:—"Cheap trimmings for doors are an abomination to both builders and users, and those who have been annoyed with loose knobs and springless bolts always feel a certain amount of pleasure when they grasp the solid furnishings of the higher-priced hardware. The knob, however, and its spindle, are not the only parts in cheap locks that are faulty; the rose, which should act as a steady for the knob, is, in the usual run of door furniture, merely a loose appendage to it, of no use but to hide the hole in the door, the tacks by which it was put on having come out by being constantly acted upon by the shoulder of the knob upon their heads, the rose having ceased to carry the knob, and become a mere hanger on; the square edges of the spindle come in contact with the wood, and you soon have a hole something like three-quarters of an inch in diameter at the face of the door, tapering down to the lock, and however good in quality the latter may be, the play of the spindle soon drags the follower askew and wears it down on one side, the latch-bolt ceases to act properly, and the lock is condemned for the fault of the furniture. There is yet another fault in the rose: the recessed centre, which should be flat, is generally, in stamped ones, so rounded off where it takes the bearing of the sharp edge of the knob as to be soon cut through by it, and the rose is then in two parts and utterly useless. The remedy is to make the recess perfectly flat, so that knob and rose may work face to face; and the way to keep the rose in its place, so that it may carry the knob square with the lock, is to make it larger and stronger, with holes in its outer edge for large screws. If our lockmakers are to keep their ground against foreign competitors, they must pay more attention to details, and not place themselves in the hands of the furniture-makers, as the failure of the knob and spindle is that which forces itself upon the notice of the user, who will probably condemn the whole for the fault of that part most constantly in use."

TREES AND DRAINAGE.

WE have heard a good deal lately from time to time about the good effect of planting the *Eucalyptus globulus*, but it would seem that some of our native or already acclimatised trees may be used with advantage where the object is to get rid of too abundant moisture in the soil. In a recent number of the *Journal of Forestry*, Messrs. Maule, of Bristol, relate how a bog in South Wales, which was not only useless but dangerous, was reclaimed by planting it with black Italian poplar. The trees grew so well that at the end of fifteen years, when they were cut down, the produce realised £13 per annum per acre for the whole period of fifteen years, during which the crop had occupied the ground, it luckily happening that the poles were wanted in the neighbouring copper works. The strong roots of the trees running through the underlying clay thoroughly drained the bog, letting off the water in such a way that no other process of draining can accomplish. In these days of great demand for packing-cases, the timber of the poplar is very valuable, and the tree has the additional property of arriving

at a fit state to be cut down in a man's lifetime. When the timber was removed, a charge of gunpowder was inserted in each stool, which effectually burst them up, and rendered their removal easy. After the ground was cleared a beautiful, rich, firm pasture remained. With reference to the drainage effected by the poplars, it seems just possible that the good effects attributed to the eucalyptus are mainly due to its rapid growth, and the drainage of the soil by the roots, which not only absorb great quantities of water, but also supply channels for the water to filter away. If this be so in this country, where we can get willows, poplars, or alders, for planting in damp places, we need not trouble about the eucalyptus.

COMPETITIONS.

IPSWICH NEW MUSEUM AND SCHOOL OF ART.—We understand that the original decision of the museum committee of the Ipswich Town Council, selecting "Pinpatch," "Bonâ Fides," and "Simplicity" as the best of the ten designs, aroused in the town much discussion and dissatisfaction. So much was this the case, that at the meeting on Wednesday week the chairman of the committee, Dr. Holden, head-master of the grammar school, gave expression to the conviction that the committee had made a mistake in the mode in which they had voted on the former occasion, and suggested that it was desirable to reconsider the matter. The previous mode of voting was simply to vote for or against each plan, but it was now decided that first of all the committee should decide which six of the ten designs were the best, each member voting for six plans. The result was that "Architect" came out first with 11 votes; "Bonâ Fides" and "Economy" equal seconds with 10 each; "Simplicity" next with 6; and "Sûvez Moi" and "Pinpatch" each received 4 votes. Next it was decided to cut these down to half, and each committeeman voting for three plans, the three highest were "Economy," 11; "Architect," 10; and "Bonâ Fides," 9. Two of the formerly selected designs were thus bowled out—"Pinpatch" and "Simplicity"—and on the final vote, the third of the original selection—"Bonâ Fides"—also had to give way, for "Architect" received 9 votes and "Economy" 5. The design of "Architect" is therefore (subject to modifications as to which a sub-committee is appointed to confer with the author) recommended to the Council for adoption. "Architect" is Mr. Horace Cheston, of 1, Winchester-buildings, E.C., who also won the premium for the best plan for converting the Public Hall into a Corn Exchange. Alternative designs were submitted by "Architect," and that which is selected is that distinguished as "red." In our review of the designs a fortnight since (p. 613) we referred to this design as compactly arranged, the museum being placed in the centre of the group. The treatment is Queen Anne.

IPSWICH POST-OFFICE.—As we intimated a fortnight ago, the recommendation of Mr. Chas. Barry, the referee appointed in this competition was favourable to the design marked "Well Considered," and it has accordingly been adopted by the Town Council. The author is Mr. J. Johnson, of Queen Victoria-street, London.

RAMSGATE NEW ROAD COMPETITION.—A meeting of the Commissioners was held at the Town Hall on Tuesday week. It had been previously understood, that Mr. Abernethy had refused to report upon the eight selected designs, which were submitted for his reconsideration. A further report upon the three premiated designs was read, but contained nothing of interest beyond a suggested general modification of "The Desideratum," and, strangely enough, it explains how the selected designs are in non-accordance with the conditions. In connection with this meeting, it had become known that the clerk would have some notes, which he had jotted down from remarks made by Mr. Abernethy, respecting the eight designs. A warm and prolonged discussion ensued, eventually a resolution was moved by Mr. Pite and carried, "That the clerk's notes of his interview with Mr. Abernethy be received, and that the reporters be requested not to publish such notes." It has leaked out that Mr. Abernethy was very severe, in this conversation or "interviewing" by the clerk, upon the re-submitted designs, especially so with regard to the designs commended by the BUILDING NEWS. It is probable however, the

motive being obvious, that these remarks will have little weight with the Board. Mr. Pearce said, "that the Board and the rate-payers ought to know Mr. Abernethy's opinion on these several plans, and they ought to have it." A small minority of the Board then endeavoured to shelve the whole question; this was defeated, and a special meeting for the consideration of the whole question, was fixed for Friday the 27th inst. (to-day). This meeting has since been postponed to Tuesday next, when we hear a very strong attempt will be made by those on the Board representing the interests of the Harbour-street tradesmen to push forward the designs which cross Harbour-street on the Level.

THE CITY OF LONDON SCHOOL COMPETITION.—The City of London School Committee still maintain their obstinate refusal to admit the competitors or the professional Press to see the designs, even in the face of a strong out-of-door feeling among the competing architects. From what we understand, action is being taken by some of the competitors, and a protest will be made to the Court of Common Council at their next meeting. Expressions of dissatisfaction become louder every day. We have already made our readers acquainted with the favourite designs, and have mentioned the features of several others, and it may be interesting to note what the school committee appointed to consider the question and obtain designs have already done in the matter as preliminary. From the report presented on the 3rd October, 1878, the question of removal of the school is discussed in detail. Seven sites were submitted by the architect, Mr. Horace Jones—namely, portion of land on Victoria Embankment, Farringdon Market, Leadenhall Market, Fumival's Inn, Hambro' Wharf, Southwark, Finsbury Circus, and Trinity-square, and the Committee wisely selected the first-named. A sum of £50,000 was considered sufficient for the erection of the schools. The Committee having decided upon the maximum number of pupils to be accommodated—viz., 680—a conference was arranged, at which the architect and head-master attended, and visits were made to the Merchant Taylors' School and Dulwich College. The architect was instructed to prepare plans, and these were submitted under the letters B and C. A quadrangular plan, with surrounding cloisters and class-rooms, formed the basis of the design. On the ground floor the class-rooms were provided on the east and west sides, with masters' and committee-room in front and covered groined cloisters on the south-west angle, the lecture-room being approached by a long corridor on the west side, forming a separate wing in the rear. On the upper floor the hall occupied the south-west corner, and is shown on the plan 105ft. by 45ft., lighted on the south and west sides; the secretary's residence formed the south-east portion, behind which is a dining-room. A second-floor plan provided for five additional class-rooms and the culinary and residential apartments. The perspective view exhibits an over-florid Gothic treatment of Perpendicular character, the hall forms the chief feature, its gabled end facing the embankment flanked on the east by a tower entrance and the master's house. The west elevation of hall is divided by buttresses, with pinnacles, into bays, each with a window, and the class-rooms behind are treated in a quieter domestic style. A large lantern or flèche crowns the centre or hall roof. In the plan C, the cloisters, with hall over, is made the front central feature, and the arrangement is certainly more compact; with four circular angle staircases projecting into the centre quadrangle. The architect's estimate was £100,000. Mr. Horace Jones's plan has been made the key-note of several of the designs, but it is unfortunate and much to be deplored that the same committee who instructed the Corporation architect to prepare designs, and who have reported upon them, should have also invited the public competition for designs. Their opinions are naturally, more or less, already made up, and consequently unable to judge fairly of the merits of other arrangements. We may remark one of the chief objections to some otherwise admirable plans is that the lighting of the school on the east side has been disregarded by building too close to the hotel.

WOLVERHAMPTON PUBLIC PARK.—On Friday a special meeting of the Park Committee of the Corporation was held, to make the final selection of designs for laying out the central portion of

the racecourse as a public park. The number of competitors had been reduced as we mentioned last week, from 27 to 3, viz., "Al Fresco," "Fortuna Sequitur," and "Spe Labor Levis." The committee decided to recommend to the council "Spe Labor Levis" for the first premium of £50 and "Fortuna Sequitur" for the second of £25, subject to a guarantee being found that the works can be carried out for £5,000.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

BRITISH ARCHÆOLOGICAL ASSOCIATION.—The closing meeting of the session was held last Wednesday; Mr. H. Syer Cuming, F.S.A. (Scot.), in the chair. It was announced amid acclamation that H.R.H. the Prince of Wales had again consented to be patron for the annual congress, which will be held at Great Yarmouth. A large number of antiquities were exhibited, among which the following call for special mention:—An alembic vessel, by the Rev. S. M. Mayhew, in the form of a dove, of Spanish workmanship, which probably contained love potions. The chairman observed that these rare vessels were made also in the signs of the Zodiac. By Mr. W. Myers, F.S.A., a classified series of terra-cotta heads from many places in Asia Minor and Italy. The nose in almost every case had been broken by the finders, and it was pointed out that this was done to prevent the finder being "haunted" by the spirit of the object represented; and by Mr. Loftus Brock, F.S.A., a series of fragments of Samian ware from Bucklersbury, among which was a name, probably that of the potter, written in cursive Latin backwards, probably one of the several inscriptions which have been read as Hebrew on similar vessels. The first paper was on the Coronation Medal of George I., Mr. G. G. Adams, F.S.A., who pointed out the poorness of the small medal by E. Hanibal, an artist of whom nothing is known. He exhibited an impression and the original die of a magnificent but unknown medal on the same subject by the well-known artist Nicholas Seelaender, and contended that this had been prepared for use rather than the other. The portrait was recognised by the Rev. S. M. Mayhew as being similar to that once at Aldgate, now in his own possession. The chairman read a paper upon St. Felix, first bishop of Dunwich, who died A.D. 650. There are sixteen saints in the Roman calendar of similar name. St. Felix is represented with the Jonquil flower. The Rev. S. M. Mayhew reported further discoveries at Lincoln. A milestone has been found standing in the centre of four great ways, as it did 1600 years ago. The inscription which has been deciphered by Mr. Wordsworth contains the name of Victorinus. The stone stands 7ft. 3in. high, and has been removed to the cathedral cloisters. A drawing of a beautiful pavement was exhibited by Mr. Parker, and it was announced that Mr. Allis had preserved several of the singular pedestals found recently. Mr. W. Morey, F.S.A., then described a remarkable Roman interment recently discovered at Hampstead Norris, and the proceedings were brought to a close by a paper by Mr. W. de Grey Birch, F.R.S.L., who called attention to the inscription on the so-called Ovin's stone in Ely Cathedral, a east of which was exhibited by the Rev. Archdeacon Emery.

CUMBERLAND AND WESTMORELAND ANTIQUARIAN AND ARCHÆOLOGICAL SOCIETY.—The first excursion of this society for the present season has been fixed for Thursday and Friday week, the 10th and 11th July, with Penrith as headquarters. On the first day Clifton Church and Hall, Nine Churches, the Countess's Pillar, and Brougham Castle will be visited. Next day the Two Lions Inn, Penrith, King Arthur's Round Table, Mayburgh, Barton Church, and the Camps in Lowther Parks and Yanwath Wood will be visited. Among the papers to be read are the following:—"A Plea for the Local Names, Part II," by Miss Powley; "Local Roman Pottery and their Marks," by R. Ferguson, M.P.; "Subterranean Carlisle," by H. U. McKie; "Recent Roman Discoveries in Cumberland—Carlisle, Botcherby, Bowness, Mowbray," by R. S. Ferguson, F.S.A.; "The Kirbythorpe Registers," by the Rev. R. Bower; "Prehistoric Find at Lorton," by J. Wilson; "The High Sheriffs of Westmoreland and Cumberland," by Sir G. Duckett, F.S.A.;

"Cumberland and Westmoreland Magistrates, Original Letters of 1688," by Sir G. Duckett, F.S.A.; "On the Practice of Mediaeval Architects and Sculptors Signing their Works," by the Rev. J. P. Hodgson; and "The Barton Registers," by the Rev. T. Hodson.

GLASGOW INSTITUTE OF ARCHITECTS.—A meeting of this institute was held on Friday last; Mr. Campbell Douglas, the president, occupied the chair, and the distribution of prizes took place. The competition was open to draughtsmen and pupils in the offices of the members of the Institute and other architects in the principal towns in Scotland. The Institute had offered a gold medal for the best design for a library and reading-room suited for a small town. The president also offered a prize for the best series of drawings illustrating the portico of St. Andrew's Church, Glasgow, with details. The drawings were publicly exhibited in the Octagon Hall, New Public Halls. For the Institute prize nine sets were submitted. The president stated that the committee appointed to award the prizes reported their opinion that the drawings given in for this prize were not of sufficient merit as to justify the medal being awarded, but, in order to mark their sense of that measure of labour and care shown, it was agreed to give a reward in books to the author of the best design. With regard to the president's prize, four sets were submitted, viz.:—A. Whitford Anderson, in the office of Messrs. James Salmon and Son, I.A.; Wm. Holmes Howie, in the office of Mr. James Boucher, I.A.; B. F. Simpson, in the office of Mr. Wm. Landless, I.A.; James Wilson, in the office of Messrs. D. M'Kissock and W. G. Rowan, architects. The prize in this competition was awarded to Mr. James Wilson. The book given was Gwilt's "Encyclopedia of Architecture." The Institute having in a former year resolved to give a gold medal annually for competition, and the President having also offered to give a prize, the following gentlemen were appointed a committee to draw up the terms of the competition for the ensuing year, viz.:—The President, Mr. James Thomson, Vice-President, and Mr. James Sellars, jun., the Treasurer. Mr. John Honeyman then adverted to a matter which had engaged the attention of the Council about a year ago, namely, the expediency of establishing a more intimate connection between the R.I.B.A. and provincial societies. The President and others having spoken generally in favour of promoting the unity of the profession, it was unanimously resolved that when the Royal Institute submit definite proposals the Glasgow Institute will give them their most favourable consideration. Before separating, the President called attention to the result of the Greenock Corporation inviting competition plans for their new municipal offices at less than the ordinary rate of architects' commission, and even less than they paid for some of their School Board work.

PARLIAMENTARY NOTES.

THE PROPOSED WIDENING OF LONDON-BRIDGE.—In the House of Lords, on Thursday week, on the motion for the third reading of the London-bridge Bill, the Earl of Carnarvon took an objection to the plans, and said that the Bill might be much better styled a Bill for the disfiguring rather than for the widening of London-bridge. He also expressed the regret he felt at the passing of a Bill some years ago authorising the construction of the railway bridge at Ludgate-hill. He suggested the postponement of the Bill. Earl Granville quite agreed with the noble earl that there were so few ornamental structures in the metropolis that every precaution ought to be taken against authorising the construction of bridges which were not of an ornamental character. He suggested that the Bill be postponed for a week. The Earl of Redesdale offered no objection, and the Bill was, therefore postponed. On the following day the Earl of Carnarvon gave notice that when the third reading of the Bill is proposed he will move its rejection. We earnestly trust Lord Carnarvon's proposal will be carried.

PREVENTION OF THAMES FLOODS.—On the motion for the second reading of the Thames River (Prevention of Floods) Bill, in the House of Lords on Monday, Lord Truro said he wished to call the attention of the Law Lords to the fact that the principle of the Bill was that

owners were to be responsible for the prevention of tidal overflow; but this was in opposition to the judgment of the Queen's Bench Division of the High Court of Justice in the case of "Hudson v. Tabor." The inhabitants of Fulham and Wandsworth complained of the application of that principle to their districts, and contended that the Metropolitan Board of Works ought to be answerable for the public streets at least. The noble lord moved an instruction to the committee on the Bill in accordance with his objections. The Bishop of London suggested that as the inhabitants of Wandsworth and Fulham had contributed their full quota to the Embankment, they ought not to be called on to afford an exceptional protection to private property. Lord Redesdale stated his opinion that as the Bill had not been introduced in the form of a public Bill, the usual notices ought to have been given; but as it had passed a Select Committee in the House of Commons, it ought to go to their Lordships' Committee unfettered. The instruction moved by Lord Truro not having been pressed, the Bill was read a second time.

TENANTS' IMPROVEMENTS IN IRISH HOUSES.—With a view to encouraging the improvement of dwelling-houses in towns and villages throughout Ireland, Major Nolan has introduced a Bill for further securing tenants' improvements in small holdings. The Irish Landlord and Tenant Act of 1870 applies only to holdings which are agricultural or pastoral. Major Nolan proposes that the first section of the Act, which renders the Ulster Tenant-Right custom legal, and the fourth section, which gives a claim to compensation in respect of improvements, shall be extended so as to apply to every holding in Ireland, of a less annual value than £50.

CHIPS.

The Penrith local board of health have approved of plans and specifications, prepared by Mr. Pollock, their surveyor, for new buildings at their water-works at Eamont bridge.

On Saturday night Mr. Alfred Andrews, builder, of Bury St. Edmund's, entertained a large party of his workmen and invited guests to the number of 150 in one of his warehouses in St. John's-street, Bury, in celebration of the marriage of his son.

Mr. Lee Turner, late surveyor of Thetford, Norfolk, has been elected borough surveyor of Cheltenham.

Another new tramway in Dublin—between Westland-row and Harcourt-street railway terminus—was opened for traffic on Monday.

The statue of King Robert the Bruce, which is to be erected on Lochmaben Hill, will be unveiled in August.

The opening lecture of the Meath Antiquarian Society was given by Sir Samuel Ferguson, R.C., LL.D., at the county courthouse, Trim, on Wednesday.

The *Revue Industrielle* says that the interior of a lead pipe can be covered with an incrustation of sulphide of lead by making a warm concentrated solution of sulphide of potash flow through it for ten or fifteen minutes. Pipes thus treated seem to be covered with a greyish varnish, which prevents the water flowing through them from acting upon the lead.

A new Wesleyan chapel at Burnham, near Bristol, built at a cost of about £1,300, was formally opened on Wednesday. Plans and specifications have been prepared by Mr. A. Lauder, of Barnstaple, and the contract entrusted to Mr. Kitch, builder, of Bridgwater. The style is Gothic, and the chapel is constructed of mountain limestone, with freestone dressings, the interior fittings being of stained pitch pine.

We understand that it has been decided to close Cooper's Hill College. It was established for the training of engineering students for the department of Public Works in India. It will, however, be some time before the institution ceases to exist, as it is not intended to interfere with the completion of the studies of those now at the college. There will, however, be no fresh admissions.

The new church of St. George, Fatfield, was consecrated by the Bishop of Durham, on Monday. The edifice has been constructed after the plans of Messrs. Austin, Johnson, and Hicks, architects, Newcastle. It is built of red brick in the Perpendicular style, and has sitting accommodation for between 300 and 400 people. Mr. G. E. Forster, of Washington, had the contract.

The Khedive of Egypt has notified to the Government of the United States his intention to present the remaining obelisk standing at Alexandria to New York.

Building Intelligence.

BATH AND WELLS DIOCESAN SOCIETIES.—The annual meeting of the board of these societies was held at Wells last week, when the following grants were made:—Erection of new church at Rowbarten, a suburb of Taunton, £300; rebuilding Upton Noble Church, £10 additional; new school-room at North Newton, near Bridgwater, £25; new class-room to school at Clenden, near Bath, £11 5s.; school apparatus, Downside, Bath, £15. The secretary was authorised to make fresh arrangements with Mr. B. Ferrey, F.S.A, the hon. diocesan architect, as to the inspection of churches in the diocese.

BATTERSEA.—The new Roman Catholic Church of Our Lady of Mount Carmel and St. Joseph was opened on Thursday week. Mr. J. Adams, of Queen's-road, Battersea, is the architect. The building accommodates between 800 and 900 persons, at a cost of £2,500. The church is in the Early English style, and consists of nave (108ft. long by 33ft. wide) and chancel. It is lofty, and has a ribbed waggon-headed roof. The whole of the benches of the church are of varnished deal, made by artisans of the congregation in their spare time as their offering to the church.

BURTON-ON-TRENT.—Mr. Roddis, sculptor, of Aston-read, Birmingham, has just completed an elaborate altar and reredos for the Roman Catholic Church of SS. Mary and Modwen, which has recently been erected at Burton-on-Trent. The centre of the reredos is formed by a richly-carved tabernacle, which rises to a height of 13ft., and is fitted with beautifully-wrought brass doors, made by Messrs. Hardman and Co. On each side of the tabernacle are niches filled with sculpture, whilst above the canopies are figures of angels. The subjects sculptured are the three patron saints of Great Britain—St. George, St. Patrick, and St. Andrew; the patron of the diocese, St. Chad; the patronesses of the church, SS. Mary and Modwen—the latter with her attributes, two swans of Trent, at her feet; and the figures of St. John and St. Francis of Sales. The lower part of the altar is divided into three compartments, the centre one being occupied by a sculptured representation of the Agnus Dei, and on either side SS. Mary and Modwen are again represented, bearing scrolls with appropriate legends. The upper part of the canopies is made extremely light, the object being to show as much as possible of the stained-glass window which will be at the back of the reredos.

EARLESTOWN.—The memorial stones of a new Wesleyan Chapel, at Earlestown, were laid on Thursday week. The length of the new building, which will be in the Italian style of architecture, will be 69ft. 4in., the width 47ft. 2in., and the height from the floor to the ceiling, 33ft. 6in. On the basement floor there will be a lecture-room, several class-rooms, a minister's vestry, a heating chamber, and a kitchen, and the height from the floor to the ceiling will be 46ft. 6in. The chapel will be constructed of Bolton red brick, with Yorkshire polished stone dressings. The lecture-room will be 43ft. 2in. in length and 39ft. wide. The cost is estimated at £5,000. The building will accommodate between 700 and 800 people. The architect is Mr. George Woodhouse, of Bolton; the builders, Messrs. Harris and Sons, of St. Helen's; and the clerk of the works, Mr. Thomas Kelly, of Bolton.

LICHFIELD CHURCH EXTENSION SOCIETY.—At a meeting of the society on the 9th inst. acknowledgments of grants paid were read from Harts-hill, Talk-o'-th'-Hill, South Normanton, Ogley Hay, Oakamoor, Caldmore, Swadlincote, Charlesworth, Penley, Wolverhampton St. Peter, West Bromwich Christchurch, and Upper Langwith. The following certificates of the completion of works were read and grants ordered to be paid:—Upper Langwith, £35; Talk-o'-th'-Hill, £205; South Normanton, £63; Caldmore, £50; and Wednesbury St. Paul, £50. The following fresh applications for aid were granted:—Hog-naston, £34; Gresley (Liuton), new church, £207; Middleton, £12; Tamworth (Glascote), £133; Stoke-on-Trent, temporary church, £75; Wolverhampton, St. Mary, do., £85; Dawley, do., £11; Mow Cop, do., iron, £45; Salop, All Saints, £156 additional; Edstaston (Glossop), parsonage, £200.

LITTLE LEIGH.—The new church of St. Michael and All Angels, Little Leigh, was consecrated on Thursday week. The church is in the Early English style, and consists of a nave 50ft. long by 20ft. 9in. wide, a choir, chancel, and north transept. The exterior of the walls are faced with Northwich facing bricks, with ornamental cornices, strings, &c., and terra cotta dressings. The inside of the walls is faced with red Northwich facing bricks. The chancel is lighted by a circular window, executed in terra cotta, beneath which, and over the altar, is a reredos, composed entirely of brick and terra cotta, the principal feature of which is a representation of Leonardo da Vinci's celebrated picture of the "Lord's Supper." This has been executed in terra cotta in alto relieve by Mr. Jabez Thomas, of Northwich. The pulpit and reading-desk are of oak, and the font consists of a red stone bowl, resting on an ornamental brick pier. Over the choir rises a bell turret of timber, covered with oak shingles. The whole of the works have been carried out by the contractor, Mr. Richard Beckett, of Hartford, from designs, and under the personal superintendence of the architect, Mr. Edmund Kirby, of Liverpool. The church will seat nearly 200 persons, and the total cost has been £2,500.

RUGELEY.—New public buildings, at a cost of about £7,000, have just been completed at Rugeley, for the local board, by Messrs. Dawson and Bradney, Wolverhampton, from the designs of Mr. Tadman Foulkes (of the firm of Messrs. Foulkes and Ryland), Town Hall Chambers, Birmingham. The style is an adaptation of the Middle Pointed or Early Decorated Gothic, the materials used being red bricks with Bath stone dressings. The construction will find accommodation for the business of the local board, the police-court, the county-court, and the market, the hall devoted to the latter being 66½ft. long (exclusive of entrance), 4ft. wide, and 40ft. high. It also comprises a caretaker's residence, a reading-room for the institution, formerly carried on in the old buildings, a fire-engine station, and an armoury for the local volunteers in the tower, which rises to a height of 90ft. above the entrance to the market hall.

SOUTHAMPTON.—A portion of the new church of St. Mary, Southampton, which is intended to form a memorial of the late Bishop Wilberforce and to replace the old parish church, was, on Thursday week, consecrated. The foundation-stone was laid on the 12th of August last, so that within a year the chancel, the chancel aisles, and vestries, and one section of the new nave have been erected and completed for use. The remaining four bays of the old church, which was erected in 1711 with materials taken from the ruins of Netley Abbey, will be taken down and replaced as soon as there are funds sufficient in hand to proceed with the work. For the part already finished the expenses incurred amount to nearly £10,000. It is estimated that a further sum of £4,000 will cover the cost of finishing the church without the spire, and that £4,000 more will be required to complete the building according to the designs of the architect—Mr. G. E. Street. The building is in the Early English style. Swange ragstone has been used for the outer walls, with Bath stone dressings, and the latter kind of stone has been employed in the interior generally, though the open tracery of the choir screens and other finer work is Cersham Down stone. The arches are decorated with dog-tooth enrichments, and a panelled and moulded stone screen encloses the chancel. The arched roof of the chancel is of panelled and moulded oak, while the roof of the nave, with moulded ribs, is of deal, as this will be decorated. The reredos from the chancel of the old church is placed in the north chancel aisle, which can be used as a chapel for morning services.

STOWE.—The church of St. John the Baptist, Stowe, was reopened, after restoration, last week. The restoration has thrown the tower into the nave, removing western gallery, and forming an arcade with new aisle on the south side. The arcade consists of three bold arches and adds greatly to the proportion and symmetry of the church. The plaster ceiling has been removed, and the present timbers, though of a rough character, have been exposed to view, and carved bosses, corbels, and pendants added, whilst the whole under side has been boarded upon the rafters. A vestry or sacristy, with heating chamber underneath, has been added on

the north-east side. The church has been re-seated throughout. The walls are unplastered, the old stones being exposed to view and pointed in black mortar. In pulling down the north wall a curious round-headed arch was discovered, which had probably been connected with a mural monument or tomb. It has been carefully preserved and rebuilt in the north wall. The stonework has been dressed and pointed inside, but outside the old stones have been used without dressing-off or disturbing the old grey coating, and the work of the new aisle is thus in harmony with the old fabric. A base and shaft of an old churchyard cross, discovered on the south side of the churchyard, have been restored and reset. The architects under whose direction the work has been designed and carried out, as also that previously done in the chancel, are Messrs. W. G. Habershon and Fawcner, 38, Bloomsbury-square, London, and Newport, Monmouthshire, the builder being Mr. Whittingham, Newport, Salop.

THURLES.—The new Roman Catholic Cathedral of the Assumption at Thurles was consecrated on Sunday. The original structure, which consists of nave, apsidal chancel, transepts, and aisles, measures 212ft. long by 120ft. across the transepts, and 75ft. across the aisles, and was erected from the designs of Mr. J. G. McCarthy, of Dublin. Many improvements and additions have been carried out under the superintendence and from the plans of Mr. G. C. Ashlin, of Dublin. These include inclosing the cathedral area by wrought-iron and gilt-headed railings, the laying of a flagged terrace round the building, approached by a western flight of steps, and the sculpturing of tympana in relief, and filling the niches with statues. Within the building a scheme of decoration has been carried out; the arcade capitals have been carved, and medallion heads of saints placed in the spandrels. The chancel has been separated from the nave by an arch supported on marble shafts with Portland stone, and also by a communion railing executed in white and coloured marbles, enriched with carving and opening with gilt metal gates. The floor of the ambulatory round the chancel has been paved with encaustic tiles, and the chancel itself has been richly furnished with archiepiscopal throne, sedilia, prebendaries' stalls, and benches for the college students, all of oak, carved. The whole 103 windows in the church have been filled with painted glass. The new pulpit is hexagonal, and of various kinds of marble; five of the six panels contain white marble reliefs of our Lord and of the Evangelists. The building works have been carried out by Mr. J. Newstead, of Fermoy; the communion-railing and pulpit by Mr. P. J. Neill, of Dublin; the oak fittings in chancel, and benches in nave, by Mr. P. Beakey, of Dublin, and the carving by Messrs. Earley and Powell, also of Dublin.

TRESCO.—The new church at Tresco, Scilly, to which we briefly referred last week in our "Notes in the West," was opened on Tuesday week. The dimensions are 81ft. by 22ft. in length, width at the transept 48ft. by 24ft., and the seating accommodation is for 250 persons. The church is cruciform in shape, and is surmounted by a small square tower, which stands on the south-east side. The roof is arched, and of pitch pine, and the whole of it, as indeed the entire main fabric of the church, has been executed by workmen on the Tresco Estate. The reredos is made of Cornish marble, and is the workmanship of Mr. Bradbury, of Penzance. The pulpit is of neatly-carved woodwork with a stone pedestal.

WIGTOWN, N.B.—A new Roman Catholic Church, at Wigtown, N.B., was recently opened. The building was designed by Mr. Garden-Brown, of Gray's-inn, London. The plan consists of a nave, apse, north and south transepts, and sacristy. The style is Early English: and, according to the *Tablet*, it is the only brick church in Scotland of any denomination. It is seated to hold about 300. The altar was the workmanship of M. Poussielgue-Rusand, of Paris. The total cost of the erection will be about £1,500.

The Wesleyan chapel in George-street, Great Grimsby, is closed to allow of alterations affording more seats and better exits from galleries and for renovation and decoration. The structural portion of the work has been placed in the hands of Mr. G. Thompson; the decorations in those of Messrs. Robinson and Emerson, also of Grimsby.

More than Fifty Thousand Replies and Letters on subjects of Universal Interest have appeared during the last ten years in the ENGLISH MECHANIC AND WORLD OF SCIENCE, most of them from the pens of the leading Scientific and Technical Authorities of the day. Thousands of original articles and scientific papers, and countless receipts and wrinkles embracing almost every subject on which it is possible to desire information have also appeared during the same period. The earliest and most accurate information respecting all new scientific discoveries and mechanical inventions is to be found in its pages, and its large circulation renders it the best medium for all advertisers who wish their announcements to be brought under the notice of manufacturers, mechanics, scientific workers, and amateurs. Price Twopenny, of all booksellers and news-vendors. Post free 2jd. Office: 31, Tavistock street, Covent-garden W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C. Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33f. 30c.). To India (via Southampton), £1 6s. 6d. To any of the Australian Colonies New Zealand, the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

N.B.—American and Belgian subscribers are requested to remit their subscriptions by International P.O.O., and to advise the publisher of the date and amount of their remittance. If the last-mentioned precaution is omitted some difficulty is very likely to arise in obtaining the amount. Back numbers can only be sent at the rate of 7d. each, the postage charged being 3d. per copy. All foreign subscriptions, unaccompanied by an additional remittance to cover the extra cost of forwarding back numbers, are commenced from the next number published after the receipt of the subscription.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—C. U.—W. J. B. P.—J. M.—F. R. and Co.—G. and Son.—J. O. B.—G. G. Co.—R. G. P.—B. of B.—J. and Co.—E. L.—T. S.

BUTLER. (There are no such competitions in connection with the Architectural Association, but those in connection with the Science and Art Department. Join the nearest School of Art, and you will get all necessary information and facilities.)—**INSURER.** (The district surveyors are elected by the Metropolitan Board of Works as vacancies occur.)

"BUILDING NEWS" DESIGNING CLUB.

EDWIN HASTE. (We think your suggestion is worth adoption.)

DRAWINGS RECEIVED.—Stefano.

Correspondence.

CURIOSITIES IN ARCHITECTURE.

To the Editor of the BUILDING NEWS.

SIR,—In your article headed "Notes in the West," reference is made to the fact that a Mr. Abbott, formerly partner in the firm of Flockton and Abbott, architects, of Sheffield, has offered gratuitous designs and a bonus of fifty pounds for the proposed new church at Newport, near Barnstaple, and further that this proposition was made after another firm of architects had by desire prepared designs for the building in question.

It may be remembered that it was Messrs. Flockton and Abbott who were the architects of that terrible iron-clad looking affair, the Albert Hall, at Sheffield, and it may not have escaped the recollection of some of your readers that when in 1875 the Prince of Wales' visit to Sheffield was anticipated, it was seriously discussed whether the Hall should not be altogether covered up with flags.

It is to be hoped that the Newport design may be different to former works, or it might—forgive the suggestion—even be dear at fifty pounds.

What would architecture come to if its votaries were all to follow in the steps of that lover of Queen Anne, who is a tile maker, and a manure-merechant as well? I had not long ago an illustrated circular sent me, wherein Lauder and Smith, of Barnstaple, introduced to my notice some remarkable designs in the way of crestsings and pots; but I had no idea at the time, although I found it out afterwards, that the first-mentioned member of the firm was an "architect."

Permit me, in view of possible business transactions, to ask whether "architects, tile makers,

and manufacturers," undertake, of course for a consideration, to cart away their own rubbish as well?—I am, &c.,
YORKSHIRE.

A SINGULAR STOUP.

SIR,—Mr. J. T. Micklethwaite thinks the curious Cornish stone at Lewanick, to which attention has been drawn, is a cresset-stone. A cresset, I take it, is an open frame, for fire or lantern, placed upon the top of a beacon; but what a cresset stone may be, I do not feel at all sure, and, no doubt, with many other readers, shall be glad of further explanation. I possess no plan of the church to refer to, but I was in it just a fortnight ago, and my memory is sufficiently trustworthy, I think, to say the following represents precisely where the stoup, or cresset, or whatever it may be, stands.

A nick, at some remote period of time, has been cut in the upper part of the side of the bowl to make it fit tightly against the projecting bead of the book-board standard. It is quite possible that the base had no original affinity with the upper part. The two are not dowelled, nor cemented together in any way; the top stone merely stands *in situ* by force of its own weight. (The circular portion) is just as heavy as I, who am an averagely strong man, can fairly lift.—I am, &c.,
HARRY HEMS.

THE WESLEYAN THEOLOGICAL COLLEGE COMPETITION.

SIR,—"Candeur" in your issue of the 20th inst., raises the old question regarding the cost of competition designs, but in this case it is hardly worth while, as it must be evident to any one who has gone closely into the subject, that £23,000 will never build what is wanted, unless the college is to be simply as plain as a cotton factory. The Committee ask—as Committees often do—what their better judgment must tell them they cannot get, so the question of cost may as well be dismissed at once, just as Mr. Barry has been obliged to do in the case of the Ipswich Post-office. A much more serious question however yet remains: I heard it stated by a competitor, when the designs were on view, that in the course of his inquiries he had "found out," the Committee would not have any plan designed on the old college arrangement of a quadrangle, that in consequence of this information he threw over a design he had commenced on this principle, and began *de novo* on another scheme; that in fact, the Committee did not want a "college" at all, in the usual sense of the word, and meant rather to discourage the idea. Now, is this so, or is it not? If it is, then the Committee are culpable in not having said so plainly in their instructions to architects; some confirmation is certainly given to the statement by the fact that not one of the prize designs is on the quadrangular principle, to the manifest

detriment of some very much better ones, which are. Should the Committee therefore, or their referee, condescend to reply to "Candeur's" remarks about the cost, it is only honestly due to those gentlemen who, relying on the fairness of the Committee, did not think it necessary to "find out" anything to the contrary.

The mention of the referee brings up the whole subject of the management of competitions. The appointment of a referee of high standing has been generally quoted as the panacea for all the evils of the system; but the result in this, as in some other cases lately, has been lamentably disappointing; apart from the question of "Principal" of plan on which the award has been made, and as to which the referee may have been acting under orders, it is clear, after an examination of the designs, that the selection was made, mainly, if not solely, on the merits of the plan alone. Now, Sir, architecture is generally allowed to be a fine art; if it is not, then let competitions be confined to arrangements of plan only, but if it is, then the artistic side of the question certainly demands more consideration than it can be said to have received in this instance. No one contends for the adoption of a bad plan for the sake of good architecture, but utility may be pushed so far as to extinguish art altogether. The arrangements of a plan can be modified by consultation much easier than the features of a design or the character of its detail can be changed from the commonplace to the artistic. In fact you may, by alteration, get a good plan; but you will never, by any process in the world, get artistic work out of a man who hasn't got it in him. In the case of this college—granting, for argument's sake, the excellence of the first prize plan, which, by the way, has nothing either of the sentiment or the traditions of a college about it—what of its architecture? With all due deference to Mr. Waterhouse's taste, it is very commonplace work. We may be told—Nothing more could be afforded. An artist can always make his work artistic, however simple. It is not said in any way that Mr. Waterhouse did not act in perfect good faith; he is much too honourable for that. He doubtless made the awards to the best of his knowledge as a practical architect, but it does not by any means follow that his judgment is infallible, or that a better selection could not have been made, alike in the interests of art and the college itself. But in planning, the selected design is really no more a college than it is art in architecture. The whole sentiment of the plan is foreign to the traditions and associations of an English Alma Mater. The class-rooms are very well arranged together, but nothing else is; and the domestic offices are in many respects very bad indeed. It may be an "institution," an "educational establishment"; it may even be the favourite arrangement of the committee, or anything else you like: it is not a college in the true sense of the word. What, then, becomes of the trust in the judgment of a referee? Simply an award according to his taste and knowledge, which may be good or bad, affecting the weal or woe of the progress of architecture just in proportion as he himself is an artist or the votary of a particular school. It is high time, Sir, that some one spoke out in the interests of architecture as a fine art, which the system of competitions, as at present conducted, is doing more than anything else to stamp out of the country.—I am, &c.,

FLORENT ARTEX.

CLEEVE ABBEY.

Sir,—In connection with a paragraph, p. 709, in your last issue, it is due to myself, and necessary to preclude any similar misapprehension in the future, to state explicitly that to my knowledge and regret Mr. Edmund Sharpe never visited Cleeve Abbey. The exhumation of the church was conducted during two months by myself, with the indispensable and cordial countenance of the owner, Mr. Luttrell, of Dunster Castle, my only assistant being Mr. Sampson, of Dunster. I gladly welcomed Mr. Ferrey, F.S.A., and Mr. J. H. Parker, who came to see the operations in progress.—I am, &c.,

MACKENZIE E. C. WILCOTT.

YORKSHIRE FINE ART AND INDUSTRIAL EXHIBITION.

Sir,—In your notice of the stained glass, the window with the subject from the "Bourgeois Gentilhomme," on the south-west stairs at the York-

shire Fine Art and Industrial Exhibition, is described as being by Messrs. Campbell and Smith. As this window is exhibited by me, and Messrs. Campbell and Smith have no connection with it whatever, I should be greatly obliged if you would correct this in your next impression.—I am, &c.,

WALTER HENSMAN.

Intercommunication.

QUESTIONS.

[5809.]-**Extras.**—Will some of your readers kindly inform me if the ordinary charge of 2½ per cent. for quantities can be charged for extras on the same building?—J. R. B.

[5810.]-**Wood Working Machinery.**—Will any reader of this journal, well acquainted with wood working machinery, kindly give his opinion on a moulding machine head, which will carry any number of moulding tools within its length without said tools being slotted? I have lately made a machine for making small mouldings, and have made the head after the above short description. I have never seen anything like the above, neither has any one to whom I have shown it. The head referred to is 6½ in. long, and will carry 10 tools ½ in. wide on each alternate square, making 20 tools in all, and two cuts in one revolution. Of course, one row of tools only can be used if required, making one cut in one revolution. I invite a candid expression of opinion on the above.—B. H.

[5811.]-**Store Floors.**—I would feel obliged by some experienced reader kindly answering the following:—What would be the best scantlings for a floor constructed of pitch pine of 23ft. 9 in. span, to carry corn? I propose running a longitudinal beam down the middle, supported by iron columns 9ft. to centres. Placed on this from wall to wall would be cross binders 6ft. centre to centres. The flooring to be of 3 in. planks, tongued with hoop iron. Would it be economical to use iron fitches in the binders? I would also like the scantlings for a similar floor of 25ft. 6 in. span. I have worked out the formule myself, but I am afraid there is some discrepancy. The factor is safety for a live load is put down as from 8 to 10 of breaking weight. Is this breaking weight in middle or distributed? Would 2½ cwt. to foot superficial be enough for weight of goods and floor itself?—SAFETY.

[5812.]-**Abroad.**—I am a clerk of works of considerable experience, a fair draughtsman, a good correspondent and book-keeper, and thoroughly conversant with office routine. Being desirous of emigrating, I would feel grateful if any of your readers who have had experience abroad would kindly favour me with their opinion as to which would be the best country to go to—Australia, New Zealand, South Africa, or America.—R. G.

REPLIES.

[5773.]-**Lime.**—As H. Ambrose seems to think I did not quote from good authority, allow me to ask how it is that the terms "poor lime" and "rich lime" are in use in the Building Construction Classes, under the Science and Art Department, South Kensington? Surely if they were not proper they would be discontinued. I have also to thank "H. A." for the latter part of his letter.—J. S. GOLDTHORP.

[5787.]-**Strain on Collar Beam Roofs.**—In reply to "S." if I were to make a couple of model roof slopes—say, 2ft. by 3ft. each and 1 in. thick, and covered with two or three thicknesses of lead to make them heavy, and hinged together at the ridge, and to have very small wheels at the lower edges or feet, and if he were to have two model walls—say, 4 in. thick and 30 in. apart, and then a number of eyes screwed into feet of roof slopes, and confine them at 32 in. apart, and were to place them on the walls, having confined them by a great number of lengths of sewing cotton strained across separately, he could remove his first tie, which had temporarily held them, and knowing the number of his threads, he could, by cutting them one at a time, and counting them, discover how many held the slopes, such being the number they broke with plus one. Now, if he were to have a groove in each underside of slopes, and a collar board fitted loosely in it would be capable of acting as the strut he speaks of; but he would at once discover that before it could be made to do duty as a strut he would first have to tie in his roof slopes, and if his collar were half way up the slope, that he would require twice the number of threads that he did at the wall level. Supposing the threads to be half way up, and this he could easily prove by having some hooks screwed in under the collar but well clear of it, and until he put the right number according to height of hooks the threads would snap, and his collar drop down the instant he removed his temporary stoppers against the feet of his roof slopes. But "S." seems to think that the walls should resist the rafters, and if so I can only remark that the rafters would be likely to thrust out his walls. It would not pay very well to build them thick for that purpose, but if so then the wall plate would be pushed off the wall. Our experiment supposes that we employ thread for ties and collars for struts, but in practice the collar, if used as a strut, could also be used as the necessary tie by the addition of bolts, and until it became strong enough to overcome the tensile strain we have seen that it could never act as a strut, and it must, I should think, be manifest to any one that when it is strong enough to overcome the tension it is still in a state of tension, because let the tension be = x, then if the strength of collar in tension be = to x y it would be absurd to say that y was in compression, because if so where would the compression come from? For how can a roof slope have a tendency to go two ways at one time? Roof slopes have a tendency to part at their feet when tied at the top or ridge, but if they were tied at their feet then "S.'s" idea with respect to the collar acting as a strut would be correct; but I beg to remind him that he supposes an absurdity—namely, the use of a collar with a tie beam underneath it, and which would really be represented by a queen-post truss, where the straining beam would be the collar he speaks of; but then why misname it a collar?—and besides, they do not put straining beams one third of the height of the

rafter from the plate to the ridge, as then the rafter only reaches up to the head of the queen-post, and further it would be no great discovery that the straining beam was in compression. Again, the word "S." uses, "concentrate," is quite inapplicable to the composition and resolution of forces in a roof with straight walls. I have not concentrated but resolved the forces at the plates and apex, and which vary according to the direction in which they are opposed, and the forces I have obtained are those consequent on the weight equally distributed on or along the rafter. "S." could also prove this by placing an equally distributed load on a large table top, and then by placing his finger under one of the four legs he would obtain a practical proof of the presence of half of the load resolved at one point, and again it is inadmissible to use the term approximation to that which we can exactly determine, that is if the word exact is to be allowed in practice as for example that $4 = 2 \times 2$. And, again, the term "equilibrium" is equally out of place, because, derived from *libra*, a balance, and if there is anything balanced in a collar beam roof, where is the fulcrum? Again, the term "centre of gravity." Although we have a centre of gravity in our roof, yet we use it not, as what we have to deal with are the extremities of gravity: the exact sciences must be dealt with with comprehension or not at all. The word "seem" is also inapplicable.—HENRY AMBROSE.

[5803.]-**Proportion in Church Architecture.**—In reply to "Perplexed Student," a well-proportioned church is one which is at least fairly satisfactory for the purpose for which it was built, and which also enraptures the vision whether seen from within or without. To design such a church it is necessary to have acquired a considerable amount of intuitive perception as to what looks best under given conditions, and as by the well-known law of permutations whereby thousands of changes may be rung upon a few bells, so may also thousands of arrangements as to design be made on that which, although

perhaps slightly altered, may nevertheless be considered as to all intents and purposes practically the same plan, and the resulting multiplicity of possible arrangements in design, some good, the majority indifferent, and no inconsiderable number being execrably bad, renders the endeavour to write rules easy to recollect and adopt at the right time and place no easy task, if indeed possible at all. It may be possible that the best method to adopt would be to know a few golden rules in planning and design, and endeavour to adopt as many as possible, and being at the same time alive to most of the mistakes previously committed by others and keeping a good look out to avoid if possible the same. In designing, it is just as well to be aware of one fact above all others, and that is that as a rule a good and masterly original design must be patiently and persistently improved, and by degrees brought as

near to perfection as possible; but to do this it will sometimes be necessary to pull the whole design to pieces several times and eliminate all that is unsuitable for that design. Let each part be in keeping with all the rest, but to achieve this it will, as an almost invariable rule, be a necessary condition that the eye and understanding shall have been under training by some means or other for several years, or the designer will generally quite unconsciously perpetrate many absurd mistakes, and which, should he continue his studies, he will, from time to time, become aware of with astonishment. Perhaps one of the very first things to achieve is good acoustical construction, and it is perhaps less generally known than it should be that the solution consists in the hearer catching the direct reflected ray of sound from the speaker, and this he can only do if there be a roof surface at a proper angle for such purpose, and this can be judged of by the following method:—Raise the height of the hearer to that of the speaker, and imagine a cord stretched from one to the other, and bisect it and strain another from the bisect in the former, and continue same to the roof, and if at any part of the roof surface it is perpendicular to the plan of same, then the acoustical points are satisfactory where tested, and if any other points will bear the same test then the building is acoustical, and, if not, then alter the pitch of roof so as to make them so. Figures 1, 2, 3, 4, 5, and 6 are good sections for the conveyance of sound. As sound reflectors perpendicular walls are next to useless, because the lower portions of them are so perforated, recessed, and obstructed by piers, &c., as to prevent radiation, and sound reflected at an inclined angle cannot be directed to the hearers, and therefore the less vertical wall there is the better, and cloistories can hardly improve acoustical properties, although they are doubtless sometimes very desirable for light. Then having determined on a section as suitable, next determine the distance the columns shall be apart in the nave arcades. I think I should generally prefer to make them from centre to centre, equal both across the nave and longitudinally. I should endeavour to avoid equality of height between—from floor to top of capital and from top of capital to vertex of arch, as not being a pleasing proportion to view. I should likewise particularly avoid putting an equal number of lights or windows in an east or west wall, as I believe such is most destructive to good effect. I would put one light, 3 lights, 5, or 7 lights, and if Early English then I would group them with a bold and effective arch of suitable curve and height, and to be generally well managed. But to revert to the arcade. Having determined the width of a bay, then determine the number of bays you will have, and I think with a good section you may easily put five bays, and then you will have obtained the plan of nave floor and width of aisles, and from which you can plan and add all else you desire. I have given examples, No. 7, 8, 9, and 10, of various kinds of arcades I might adopt in preference to some others. I should avoid where possible the obtaining wall spaces of unseemly shape above the chancel arch and under roof, and likewise at the west wall, as, however well such may be filled up, the leading lines will continue to dominate and compel thee to discern that something has not yet been altogether successfully arranged. With respect to chancels, apses, towers, and spires, &c., they would run beyond the limits of this paper. —HENRY AMBROSE.

[5805].—**Eddystone Lighthouse.**—So far as I am aware there is no record of the cost of the three lighthouses built on the Eddystone rock. Winstanley commenced his in 1696, and it was finished three years afterwards. It was of wood, 100ft. high, and had an open gallery at the top. During a fearful storm in 1703, and whilst Winstanley was in it, the building was completely washed away. Mr. Henry Winstanley was an Essex country gentleman, an amateur, but a man of singular mechanical ingenuity. Three years afterwards, in 1706, John Rudyerd, a silk mercer, of Ludgate-hill, E.C., commenced his work upon the same spot. Choosing the frustum of a cone for his model, he built up five courses of heavy stone upon the rock, and thereon erected a superstructure of wood. This stood well and worked admirably until the end of 1755, when it was unfortunately destroyed by fire. It was afterwards that Smeaton designed the present beautiful lighthouse, the foundation-stone of which was laid in June, 1757, and the structure completed in August, 1759. It is particularly interesting in that in its day it was foremost of almost all other lighthouses. The only other stone-built rock beacon in the world was the Tour de Cordeuan, in the Bay of Biscay, a tower 97ft. high, erected on a spacious flat rock at the mouth of the Garonne, in the 16th century. Half a century after the Eddystone the Bell Rock Tower, on the Inch Cape Reef, was built, with an altitude of 100ft. Forty years ago Mr. Alan Stevenson built the Skerryvore lighthouse on the West Coast of Scotland, which is 138ft., and its bulk five times that of the Eddystone. The present Eddystone is 80ft high, and upon the upper course of granite beneath the ceiling encircling the upper room runs the homely:—

"Except the Lord build the house
They labour in vain that build it."

The engineer for the new lighthouse is Mr. James W. Douglas, consulting engineer of the Trinity Board, a gentleman of great ability, and the constructor, I believe, of the lighthouse at Hartland, St. Catherine, Isle of Wight; St. Judwall, North Wales, and the Casquets, off Guernsey. The new lighthouse at the Eddystone will stand 132ft. above the level of the highest spring tide. At one time it was mooted to remove the rock altogether, but that would have involved the shifting of 2,000,000 tons of stone, at a probable cost of £500,000, so that idea was given up. The new job was open for competition some little time ago, and Mr. John Petrick's tender for the lighthouse was £100,000. The Elder Brethren of Trinity House, however, considered they could carry out the work for some £30,000 less than that, and so, under the superintendence of Mr. Thomas Edmond, the resident engineer, the works have begun, and it is expected they will be completed in about three years. The workmen are paid 30 shillings a week, and an additional 6d. per hour afloat, and 6d. extra again an hour when at work fixing, &c., upon the rock. Forty men are employed upon the job, which lies 127ft. away from Smeaton's present tower. The granite blocks that will be used will average 3 tons each. They are first brought from Messrs. Sheares, Smith, and Co.'s quarries, at Wadebridge, ready dressed, to the Trinity Yard, at Oreston, near Plymouth, are fitted in their courses there, and will then be conveyed

in the floating Hercules to the reef, 14 miles distant. The Hercules was built purposely for this class of work by the Trinity Board. Her engines are adopted for lifting and pumping, as well as for locomotion; smiths' shops are on board, powerful winches, and her bows are fitted with "gallows," by which practically any weight can be put ashore from the deck. Mr. W. T. Douglas, son of the architect himself, is appointed assistant engineer on the works. —HARRY HEMS.

[5806].—**Builder's Day Account.**—The building committee have a right to dispute your charges, and to employ a surveyor to measure and value your work. You are not obliged to accept the surveyor's valuation. Sue the committee. I make no doubt they will pay into court the sum of the valuation made by the surveyor, and that the judge will order an arbitration on the balance. Judges as a rule will not give their judgment on builders' accounts, which are complicated and can only be judged by a competent and disinterested surveyor, chosen mutually by both parties. —WILLIAM JACKSON.

STAINED GLASS.

CHICHESTER.—A somewhat remarkable example of French glass is in process of insertion in the famous south transept window at Chichester Cathedral, well known as one of the finest examples of the Early Decorated style. The stained glass which originally filled it was destroyed by Waller's pikemen at the Great Rebellion; and years ago, whilst the new tower and spire were building, Mr. Abel Smith, then M.P. for Chichester, promised to repair the damage thus done to the effect of the church. He died, however, before carrying out his purpose, but his family liberally volunteered to do what their father had intended, and selected a French artist (M. Champigullo, of Bar-le-Duc) to execute the work. The Franco-German war for a long time suspended all operations; and it is only now, says the *Guardian*, when nearly every member of the Chapter which originally accepted the gift has passed away, that the window has been completed.

LEGAL INTELLIGENCE.

ADVERTISEMENT HOARDINGS.—At Marylebone, Messrs. Langmead and Way, builders, of Gray's-inn-road, were summoned on Tuesday, by Mr. Henry Tomkins, surveyor for the parish of St. Marylebone, for continuing a certain hoarding or fence at Nos. 119 and 120, Oxford-street, for the purpose of depositing bricks or other materials, in a manner not permitted by a certain licence granted by the Vestry of Marylebone to them on the 10th of May, 1879, for a period of 10 days beyond the 5th day of June, on which day a penalty of £1 was inflicted on them for erecting such hoarding, contrary to the aforesaid licence. The defendants were contractors for rebuilding Nos. 119 and 120, Oxford-street, and they, having obtained a licence from the Vestry for the erection of a hoarding outside the premises on the public way, to the height of 10ft., erected one 25ft. high, and it was let to Messrs. Willing, the advertisement contractors, and was covered with bills. For not erecting the hoarding in accordance with the licence the defendants were summoned before Mr. D'Eyncourt, who was then sitting at this court, and fined £1. Subsequently his worship was asked to grant a case, but he refused to do so. It was now stated that the owners of the premises in their contract with the defendants, reserved to themselves the right to let the outside for advertisement purposes, and they let the hoarding to Messrs. Willing for £10 a month. Six days after the defendants were fined, Messrs. Willing decided to have nothing further to do with the hoarding, and on the 18th the defendants proceeded to pull it down. The Vestry did not ask for the penalty beyond the 11th. For the defence it was urged that the defendants, though legally responsible, had no power in the matter, the owners having reserved to themselves the power to let the hoarding. Mr. Greenwell said that these high hoardings were injurious to the business of shopkeepers on either side, and the fact that builders received money from advertisement contractors was often an inducement for them to keep these unsightly structures up for an unnecessary time. Mr. De Rutzen said that the defendants must be held liable for allowing the hoarding to remain after the order, and there would be a fine of 10s. a day for five days, that being from the day of the order to the 11th.

IMPORTANT BUILDING TRADE CASE.—At the Stourbridge County Court on Monday, before Mr. Rupert Kettle, a case was tried in which the plaintiff, Mr. D. Hawkins, of Cheltenham, a quantity surveyor, sued Mr. C. E. Horton, contractor, Brierly Hill, Staffordshire, for £28 for taking out quantities for work done for Mr. F. Evers, J.P., a gentleman of that neighbourhood. The defendant did not dispute the liability, but he had declined to pay the money owing to there being a second claimant for it in the person of Mr. Smalman Smith, the architect to the work referred to. The case had been once before the Court before, a decision being given in favour of the plaintiff, but it now came on for a new trial before a jury. The plaintiff's case was that it was usual to pay 2 per

cent. commission to the quantity surveyor who took out the quantities for any contract; that he did so in this instance, and that the money in question was thereupon due to him. In cross-examination plaintiff said he was engaged as clerk of the works to the Stourbridge School Board and Stourbridge Burial Board in 1876, and that his engagement permitted him to do other work. It was while clerk of the works to the above buildings that he got out the quantities in this case. The quantity surveyor was responsible to the builder for the quantities. He could not say whether he signed the quantities upon which Mr. Horton tendered. The document being handed to him, witness said he did not sign. It was not necessary for him to do so, as he was known as the quantity surveyor, and saw defendant regarding the quantities. He took out a number of other quantities for work with which Mr. Smalman Smith was connected. He signed a number of them. Pressed as to this, he said he signed five, and that he did so when they originally issued. He was to have the whole of the commission for these quantities. It was not to be divided between Mr. Smith and himself. It was not usual for an architect to employ a quantity surveyor to take such quantities and allow him half the commission. He admitted being the writer of the letter to a builder, produced. In it he asked the builder to write him a document to be used in the case in his own favour, and a form for which he inclosed. Plaintiff was cross-examined as to his antecedents, to show he was not a man who could have afforded to wait for his money, as he had done, if the 2 per cent. was really due to him. Counsel for the defence called evidence to prove that plaintiff was employed by Mr. Smalman Smith to take out the quantities, and it was stated by Mr. Smith that he agreed to give plaintiff 1 per cent. for this work. It was also stated that when a quantity surveyor took out quantities on his own account he endorsed his name upon them as responsible for the figures. Where there was no name, however, the architect was responsible for them. In this instance, there being no name, the plaintiff was not specified as being responsible for them, and counsel argued that Mr. Smith was. Mr. F. Evers was called, and said he instructed Mr. Smith to have the quantities taken out. (Counsel called attention to a rule of the Institute of British Architects allowing architects to take out quantities where an employer permitted.) The evidence of defendant was to the effect that he was supplied with the bills of quantities by Hawkins. He should have looked to plaintiff as responsible if the quantities had not been right. If there had been an error in them he should have had to look to Mr. Evers. His first tender was not accepted, and he went through the quantities with the plaintiff and reduced it. His first application from plaintiff was by a lawyer's letter.—Mr. Smalman Smith, architect, in examination, stated positively that he employed the plaintiff Hawkins to take out the quantities, and that he agreed to give him 1 per cent. for doing so.—Mr. Randle, architect, Shrewsbury; Mr. James Binnicau, builder, Kidderminster; Mr. John Nurse, quantity surveyor to Mr. Pountney Smith, Shrewsbury, were examined in support of the contention as to the architect being regarded as responsible for the quantities when there was no surveyor's name on the bills of quantities.—His Honour, in summing up, said the question as to the alleged agreement between Mr. Smith and plaintiff, that the former should pay him half the commission, had nothing to do with defendant, and was only a collateral point. Referring to the conflict of evidence, his Honour said they should look to whether the conduct of the men who gave evidence contradictory of each other were consistent or inconsistent with what they stated; and in the progress of his comments on the evidence, his direction to the jury as to the points for their consideration, rather bore in plaintiff's favour. The jury, after a long consultation, and being thrice summoned into court, could not agree, and it was at last agreed to take the verdict of the majority. Four were for the defendant, and one for the plaintiff, and a verdict was entered for the former. A number of other cases hung upon this decision.

POOR WORKMANSHIP.—At Poulton County Court on Wednesday week an action was brought by Lingard, builder, against one Eaves, to recover £18, balance of an account in respect of a contract for building done involving £144. Plaintiff deposed that he built three houses at Sunnyside, Kirkham, for defendant, at a contract price of £144. No complaint as to joinery was made at the time of completion, and £126 had been paid on account. The defence was that the slating and other works were badly done. Mr. Robert Cross, architect, deposed that he had examined the plans and specifications, and the buildings, and had come to the conclusion that some of the work was so imperfectly done that £9 15s. ought to be deducted from the amount of the contract. Mr. Langley having given corroborative evidence, a verdict was entered for plaintiff for £9 15s. 11d.

WHAT IS A BUILDING?—A case important to

builders and others was heard on Wednesday at the Liverpool police-court, before Mr. Raffles. Messrs. S. Campbell and Co., contractors, Pudsey-street, were summoned for erecting a shed in Dexter-street, and infringing the Building Act by not building the outer walls and party wall of the said shed of brick or stone. Mr. Atkinson, deputy town clerk, prosecuted, and said that according to the law no erection which was of wood could be built in Liverpool. There was a case bearing upon the point decided in the Court of Common Pleas. According to the Metropolitan Building Act, it was stated "that every building shall be inclosed with walls constructed of brick, stone, or other hard and incombustible material, and the foundation shall rest on the solid ground, or upon concrete, or upon other solid substructure." A person erected a shop all in wood, without footings or any brickwork for a foundation. The question was whether the shop was a building within the meaning of the Building Act, and this point the Court of Common Pleas was asked to decide. Mr. Justice Williams held that the shop was a building within the meaning of the Act, and that it prohibited building the walls of wood or other combustible substance. Mr. Justice Byles also held that a church built of iron or of wood, or a stable or a coachhouse, is a building, but that a birdcage with a handle to it for lifting it off the ground, or a wig-box, is not a building. He (Mr. Atkinson) need not say that he would not prosecute in the case of a birdcage or a wig-box. The present case was a very serious one. It was in direct contravention of the Building Act, for it was a building inclosed with wood, in fact, in every sense a wooden building, which was not allowed by the law of Liverpool.—Mr. Campbell, for the defence, contended that there had been no infringement of the law. The place complained of was simply a shed made to allow four carriages to be run under it in case of rain.—Mr. Goldstraw, building surveyor, said it was a building inclosed with walls half of brick and half of wood.—Mr. Campbell said the question was one of great importance to contractors of all degrees in Liverpool and their clients, who might wish wooden erections to be placed upon their vacant land until such time as it might be built upon by some more permanent erections. The owner of the land in question employed him to build a temporary shed; it was simply a roof of corrugated iron being placed upon four posts. It was not connected with the old brick walls, and did not in any way come within the meaning of the Building Act. When he received an intimation that it was in contravention of the law he went and saw Mr. Hunter, one of the most experienced of the building surveyors, and he had given him authority that there was nothing in contravention of the Act, and he went on building. It was similar to the adjoining shed, which had been up for several months.—Mr. Goldstraw said this was not so.—Mr. Campbell again urged that this shed was not a building within the meaning of the Act. It was not a shed even in that sense; it was a roof upon ten props.—Mr. Atkinson: That we simply deny.—Mr. Goldstraw said the place was inclosed with wood.—Mr. Hunter was called.—Mr. Raffles: Did you give him authority to erect this place?—Mr. Hunter: I could not. It is not in my district.—Mr. Campbell: Do you remember my coming to your office and showing you this plan? Mr. Hunter: I remember nothing about it.—Mr. Campbell: Did I show you these plans? Mr. Hunter: Very likely you did. I can scarcely remember. I said if you kept away from the thoroughfare or any other building, it would not be wrong; but I could not give you any permission.—Mr. Atkinson said that the law required that a building should be of brick or stone. Since the Act came into operation the making of buildings of iron had become very popular; and although they were not strictly in accordance with the law, the authorities did not object to them.—Mr. Campbell said the place in question did not come within the meaning of the section under which the summons was laid, but under the fifth rate schedule. If it was wrong, what became of the many erections of a similar kind that had been allowed by the surveyors?—Mr. Raffles (to Mr. Campbell): I think the law is against you. I will adjourn the case. If it comes before me again, and if you have not satisfied the health committee, I will inflict a penalty.—Mr. Atkinson: These buildings are dangerous.—Mr. Campbell: Then they should not be permitted anywhere.—Mr. Atkinson: And they will not be if I can help it.—The case was then adjourned.

The Swansea harbour trustees have entered into a contract for the immediate construction of the long-contemplated docks at Fabion's bay. This decision has aroused action on the part of the Neath harbour commissioners, who have invited tenders for £200,000 in mortgage bonds of £100 each. Their intention is to provide floating dock accommodation at Neath by means of a navigable cut, which will divert the stream and will enable the present bed of the river to be used for that purpose.

Our Office Table.

Mr. G. E. STREET asks, in the *Times*, "Is it too late to make a last appeal on behalf of London-bridge? No one has yet been found bold enough to say that the scheme for its alteration now before Parliament is anything less than a scheme for its destruction. And the only plea I have seen in its favour is the scandalous one (as it seems to me) that it is economical. Are we come to this, that we are ready to destroy one of the few fine bridges we possess with a view to economy? At least, could we not leave it alone until the Tower-bridge question is settled? Twice lately I have crossed London-bridge in a cab at a trot, and without a crowd. And, as we all know, some who ought to be authorities hold very decidedly that the alteration of the bridge alone will do no good when there is a crowd. We do not, unfortunately, do much building work that has any monumental character. Our engineers no longer appear to concern themselves on this point. We may well be proud of Rennie as of one who set them a noble example. But if we destroy his work within about half a century of its erection, what encouragement is there to his successors to follow in his footsteps? Nearly four years ago you were so good as to allow me to protest against this scheme, and as I was the first, so, if it must be, I will be the last also to protest against a work which seems to me to be unworthy of a civilised age and city." From first to last we, too, have protested against the unequalled interference with Rennie's bridge. We have urged that the adoption of the proposal to widen it will not relieve the traffic in the slightest, and we do not believe, even now, that Parliament will allow the City of London to carry out its scheme.

The Hemel Hempstead Highway Board are about to build a new bridge over the river Gade, thirty feet long and eighteen wide, and are inviting competition plans for the same under rather remarkable conditions. The members of the board disagree as to the advisability of constructing the bridge of iron, of wood, or partly of both materials, and so they very coolly invite the competing engineers to send in three separate sets of plans and estimates, all at their own expense and within a period of twenty days! A similar invitation is issued with regard to a smaller bridge to be partially reconstructed in the same neighbourhood; in both cases the parties competing are to tender for the execution of the work, and in neither do the board guarantee the acceptance of any tender. From time to time we record some remarkable instances of ignorance of the value of the time and labour of professional men on the part of local boards and similar bodies, but we do not remember before to have come across such a unique example as that just referred to. One economical member of this most economical highway board, remarks, in the discussion which took place at the last meeting, that it would be best to make the bridge of wood as it was unwise to do too much for future generations, the present generation having expenses enough of its own. Competitors who feel inclined to contribute towards the relief of the present generation had better write to Hemel Hempstead at once for particulars.

HERE is another instance of the way in which Local Boards manage their business. Contractors are put to the trouble and expense of tendering, and are then politely informed that the plans and specifications were wrong, and they had better tender again. At a meeting of the Rural Sanitary Authority of the Loughborough Union held last week, the committee appointed to examine the specifications and quantities prepared by the engineer, and consider the several tenders received for the execution of the drainage works at Sheepshed, recommended the Board not to accept any of the tenders, but to direct the engineer to amend the plans and specifications, so that the contract would include the whole of the work required to be done. The committee were of opinion that if any of the tenders received were accepted, there would be large claims for extras. The recommendations of the committee were adopted by the Sanitary Authority; and Mr. Stephens, the engineer, who was in attendance, was instructed to prepare plans and sections of the work required on the

sewage farm, so that the same might be included in the contract; and to amend the specifications and quantities in the several particulars mentioned by the committee in their report, and to submit them for the approval of the authority. The clerk was instructed to inform the persons who had tendered that the Sanitary Authority had decided to amend the specifications and quantities, and that they would then re-advertise for tenders for the works required.

MESSRS. T. ROBINSON AND SON, of Roehdale, will exhibit at stand No. 483, in operation at the forthcoming International Show, to be held at Kilburn, on Monday next, and six following days, a new patent machine for tooling and dressing stone, which from its great utility in economising the working of stone over hand-labour, and the superior quality of work turned out, will prove of considerable novelty.

MR. RASSAM has arrived in England, having completed the programme of his explorations in Mesopotamia for the present year. Although the expedition has been hampered by the illness of Mr. Rassam, archaeologists will have no cause for dissatisfaction with the results. A considerable time has been devoted by the explorer to the solution of the relative positions of the edifices on the mound of Ballawat, from which he obtained the rich bronze gates, and there is every reason to believe that we may now have a complete plan of the site. In the mound of Kon-yunjik, the site of Nineveh, Mr. Rassam has continued his explorations in the ruins of the palaces of Sennacherib and Assurbanipal, and he brings to England a number of inscriptions in stone and terra-cotta which he has obtained from those sites. During a visit to Bagdad, Mr. Rassam succeeded in acquiring from the local dealers a fine collection of Babylonian inscriptions, many of which are of an extremely interesting character. Among these are a further instalment of the Egibi tablets, which have already proved of so much importance in the settlement of Babylonian chronology.

A LONG discussion took place at the meeting of the Liverpool Town Council, this week, upon a resolution of the Health Committee recommending that the superintendent of the sewerage department, Mr. John Evans, should be requested to resign, and that two foremen should be dismissed. Recently several sewers were examined by a special committee, when it was discovered that in six of them the workmanship was defective, the mortar and cement of poor quality, and in some cases only one course of bricks had been laid where there should have been two. Mr. Evans had charge of the sewers in question, and the allegation against him was that he had not exercised a proper oversight. The recommendation of the committee was opposed on the ground that dismissal was too severe a punishment considering the thirty-one years' service of Mr. Evans, but ultimately it was agreed to by twenty-seven votes to ten; and it was also decided that the whole subject of the staff and organisation of the engineer's department should be dealt with at a special meeting of the Health Committee.

A SUPPLEMENTAL report on the electric lighting of Holborn Viaduct has been submitted to the Commissioners of Sewers for the City of London by their engineer, Mr. Haywood. These are based on the photometric observations on the Embankment lights, made for the Metropolitan Board of Works by its engineer-in-chief and consulting chemist jointly. Upon the data those officials furnish, which assign to the electric light much less illuminating power than was claimed for it by the Société Générale d'Electricité, Mr. Haywood calculates that the electric light on the Viaduct, when naked, gave about five times that of the ordinary gaslight, and as inclosed in opal globes, about twice as much. Applying the present cost of the Embankment experiments (5.73d. per lamp per hour) to those on the Viaduct, and assuming the lamps to be kept alight 4,300 hours annually, the same as the gaslamps, the yearly cost would be, for the 16 electric lamps, £1,642 12s., and for the 86 gaslamps, £419, thus showing that the former means of illumination is nearly fourfold the cost of that ordinarily employed. If, however, the time occupied in lighting and extinguishing the gaslamps, about half an hour daily, be taken into account, the electric light would be burning about 4,117 hours per annum at a cost of £1,572 17s. 8d., or about 3½ times as much as gas.
